A FURTHER EVALUATION OF ARTIFICIAL PNEUMOTHORAX IN LOBAR PNEUMONIA

CHAIRMAN'S ADDRESS

FRANCIS G. BLAKE, M.D.
NEW HAVEN, CONN.

In previous reports¹ on the treatment of lobar pneumonia with artificial pneumothorax it was pointed out that no evidence of beneficial effect on the duration or outcome of the disease was obtained in late cases of more than seventy-two hours' duration or in earlier cases with pleural adhesions which prevented adequate collapse and immobilization of the involved lung. Of fourteen late cases eight showed spread to other lobes, empyema developed in two and there were nine deaths. In twelve early cases with adhesions the expected duration of the disease was not obviously shortened in eleven, four showed further spread of the pneumonia, empyema developed in two and there was one death.

Of the total group of forty-two cases there remained sixteen without pleural adhesions in which treatment was started prior to seventy-two hours after onset. Concerning six of these, first treated between forty-eight and seventy-two hours after onset, it was stated that, although all appeared to be benefited, the apparent prompt improvement was of doubtful significance in view of the early appearance of antibodies in three and the occurrence of relapse after initial improvement in two. Of the remaining ten, first treated prior to forty-eight hours after onset, all showed relief of symptoms with prompt recovery by crisis in five and apparently accelerated recovery by lysis in four. In none could the short course be attributed to the early appearance of antibodies. In spite of the noteworthy fact that none of these ten patients happened to be bacteremic, the response nevertheless seemed sufficiently encouraging to warrant further study in an effort to reach a more definite opinion concerning the possible value and already fairly obvious limitation of artificial pneumothorax therapy. With this in view thirty additional cases have been treated, the pertinent data being presented in tables 1 and 2. The procedure followed was

that previously described,¹ namely the induction and maintenance of complete collapse of the lung on the involved side, so far as this was possible.

Analysis of the results in these additional cases serves first to confirm the limitations previously pointed out. Of the thirty cases, three (10, 11 and 12, table 1) were treated later than seventy-two hours after onset. One, patient 10, showed further spread of the pneumonia and died. One, patient 11, though promptly relieved of pleural pain, had an otherwise natural course, recovering by lysis concurrently with the appearance of agglutinins in the blood, while the third, patient 12, also promptly relieved of pleural pain, had an immediate crisis; but this was not unexpected, as a pseudocrisis had already occurred on the fourth day. Nine earlier patients, also shown in table 1, turned out to have pleural adhesions which prevented adequate collapse. In none of these was the course favorably affected. Six had spread of the pneumonia to other lobes, one had empyema, six died.

There remain eighteen cases without pleural adhesions in which treatment was initiated prior to sixty hours after onset (table 2). Of these, four (13, 21, 25 and 28) showed prompt recovery by crisis, but patient 21 must be eliminated because of simultaneous treatment with type I antipneumococcus serum. Seven other patients (17, 19, 22, 23, 24, 27 and 29), three of whom were bacteremic, appeared to be clinically improved and recovered by lysis without further spread of the pneumonia. On the other hand the clinical course was not favorably modified in seven. Four of these showed further spread of the pneumonia, two had empyema, and three died.

COMMENT

Analysis of the course of events in the total series of thirty-three² early cases in which pleural adhesions were not present, summarized in table 3, would seem to suggest that artificial pneumothorax treatment is of definite value not only in providing relief from pleural pain but also in beneficially affecting the course and outcome of the disease in those cases in which satisfactory collapse can be promptly established. Recovery of approximately one half of the patients before or by the fifth day indicates a much shorter average duration than usual and the case fatality percentage is quite low. Furthermore, comparison of the results with those in the concurrently treated group of early cases in which pleural adhesions were present so that adequate collapse could not be established, shows a striking contrast between the two groups with respect to duration of the acute febrile stage, frequency of further spread of the pneumonia, subsequent development of bacteremia, inci-

From the Department of Internal Medicine, Yale University School of Medicine.

Read before the Section on Practice of Medicine at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

This investigation has been made with the assistance of grants from the Committee on Therapeutic Research, Council on Pharmacy and Chemistry, American Medical Association, and the Research Fund of Yale University School of Medicine.

dence of empyema and the number of deaths (table 3). Obviously, however, an analysis of factors other than the absence or presence of pleural adhesions which might have influenced the results is essential before the apparently good results in the group without pleural adhesions can justifiably be attributed to treatment with artificial pneumothorax. Some of the factors which can be compared are the relative frequency of the different pneumococcus types, the distribution of cases according to age, the time in twenty-four hour periods after onset when treatment was started, the number of lobes already involved when treatment was begun, and the presence

in the group with adhesions as in the group without adhesions. In only one important respect does the group without adhesions lack a chance advantage, namely in the proportion of patients initially bacteremic, but even here the apparent equivalence must be discounted as one of the three type I bacteremic patients in the non-adhesion group received antipneumococcus serum simultaneously with pneumothorax therapy and three had infections due to pneumococcus types IV, VIII and XXXI, respectively, with blood cultures which showed less than one colony per cubic centimeter of blood, while two of the three bacteremic patients with pleural

* Pneumococcus group IV, type not determined.

of bacteremia prior to treatment. From the analysis shown in chart I, it is at once apparent that a smaller proportion of the cases without adhesions were due to types I, II and III pneumococci, a much larger proportion to the other types than was the case in the group with adhesions. It also happens that the ratio of younger patients under 40 years of age to older patients is nearly twice as large in the group without adhesions as in the group with adhesions. Furthermore, nine of the former group were treated within twenty-four hours after onset as contrasted with only one of the latter group, a fact which might provide a chance advantage to the group without adhesions, at least so far as earlier recovery is concerned. Finally, the proportion of patients with more than one lobe involved when treatment was started is six and a half times as great

adhesions showed ten and thirty-four colonies per cubic centimeter, respectively.

In spite of these several advantages possessed by the group without pleural adhesions, comparison of the two groups subdivided according to pneumococcus type, time of treatment and age still shows in each comparable subdivision a much better result in the group without adhesions (table 4), which might seem to justify the conclusion that artificial pneumothorax therapy is of definite value in lobar pneumonia. For example, of fifteen patients without adhesions treated between twenty-four and forty-eight hours after onset, of which five were bacteremic, six had recovered on or before the fifth day as contrasted with none of the ten with adhesions, of which only two were bacteremic. Similarly, of eighteen patients without adhesions, from 30 to 49 years of age,

nine had recovered by the fifth day or earlier as against none of the twelve patients with adhesions.

A really critical evaluation, however, demands that all the favorable and unfavorable factors enumerated which might influence the outcome independently of pneumothorax therapy be simultaneously taken into consideration. If this is done, as shown in chart 2, it will be found that eight, or 23.5 per cent, of the group without adhesions as against one, or 4.8 per cent, of the

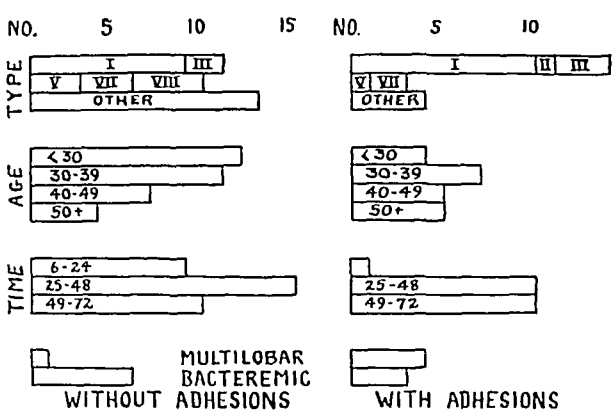

Chart 1.—Distribution of cases according to pneumococcus type, age, time of treatment in hours after onset, involvement of more than one lobe and bacteremia.

group with adhesions fall into the most favorable classification, i. e., nonbacteremic, unilobar, pneumococcus group IV patients under 40 years of age and first treated less than thirty-six hours after onset. Even more significant is the fact that seven, or 33 1/3 per cent, of the group with adhesions as against only two, or 5.9 per cent, of the nonadhesion group fall into the unfavorable classification of patients over 40 with infection due to pneumococcus types I or III. Five of the seven fatal cases in the group with adhesions are found here. The analysis might be carried further but this seems hardly necessary, since it would serve only to confirm the fact,

already obvious, that the apparently favorable results in the group without adhesions cannot justifiably be attributed to the effect of artificial pneumothorax therapy but are much more probably due to the initial advantages which this group possessed.

A similar type of analysis, so essential to adequate evaluation, cannot be applied to all the cases recorded in the literature, since the necessary data are lacking in many of them. Reports³ which have appeared since our

previous review,⁴ however, as most of the authors conclude, fail to provide convincing evidence that artificial pneumothorax is a curative procedure, even though symptomatic relief, particularly of pleural pain, is undoubtedly seen in many cases. Especially significant

is the apparent failure of artificial pneumothorax to check bacteremia consistently when present and invariably to prevent its subsequent development in patients who are nonbacteremic when treatment is instituted.

SUMMARY

Seventy-two patients with lobar pneumonia have been treated with artificial pneumothorax. Effort to evaluate the therapeutic usefulness of this procedure. It has been found to be of no value (1) in late cases of more than seventy-two hours duration and (2) in earlier cases with pleural adhesions which interfere with

Chart 2.—Analysis of factors influencing course and outcome. Numbers indicate pneumococcus type: without circles, without pleural adhesions; in circles, with pleural adhesions; +, bacteremic; M, multilobar; D, died.

adequate collapse of the lung. These two facts alone would seriously limit its field of possible usefulness, even were it of value in early cases without pleural adhesions, since many patients do not present themselves until late and adhesions are found in approximately 30 to 40 per cent of early cases. A further important limitation is the fact that it has not been found to exert a demonstrable effect on an established

bacteremia nor does it necessarily prevent subsequent invasion of the blood by pneumococci.

Although the course and outcome in the majority of thirty-three early cases without adhesions would appear, on first analysis, to have been beneficially modified by treatment with artificial pneumothorax, a careful evaluation of other factors which might have been responsible for the apparently good results renders such a conclusion untenable.

CONCLUSION

Artificial pneumothorax would appear to be of value for the relief of pleural pain in selected early cases of lobar pneumonia. It has not been demonstrated that it possesses any curative value in this disease.

THE TREATMENT OF SUBCLINICAL AND CLASSIC PELLAGRA

USE OF NICOTINIC ACID, NICOTINIC ACID AMIDE AND SODIUM NICOTINATE, WITH SPECIAL REFERENCE TO THE VASODILATOR ACTION AND THE EFFECT ON MENTAL SYMPTOMS

TOM DOUGLAS SPIES, M.D.

WILLIAM BENNETT BEAN, M.D.

CINCINNATI

AND

ROBERT E. STONE, M.D.

BIRMINGHAM, ALA.

The observations of Elvehjem, Madden, Strong and Woolley¹ showing that nicotinic acid cures canine black-tongue stimulated several investigators to administer nicotinic acid to human beings with pellagra. Their reports have been reviewed elsewhere.² Spies, Cooper and Blankenhorn² recently reported that in a series of seventeen cases of pellagra, nicotinic acid, nicotinic acid amide and sodium nicotinate dramatically blanched the erythematous dermal lesions, produced healing of the glossitis, stomatitis, vaginitis, urethritis and proctitis, and reduced the amount of porphyrin in the urine to normal. These authors also described flushing, burning and itching of the skin following the administration of massive doses of these drugs. In view of these observations it seemed desirable to determine the effect of nicotinic acid, of its amide, sodium salt and diethyl amide (coramine) and of trigonelline (the methylbetaine of nicotinic acid) on manifestations of pellagra other than those mentioned and to investigate further their pharmacologic and therapeutic action. The present report is concerned with the effect of these drugs on normal human beings and on persons with pellagra, in addition to those patients previously described by Spies, Cooper and Blankenhorn.

From the departments of medicine of the Cincinnati General Hospital and the Hillman Hospital of Birmingham, Ala.
Read before the Section on Pharmacology and Therapeutics at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

This investigation was aided by grants to the University of Cincinnati College of Medicine from the Rockefeller Foundation, the Josiah Macy Jr. Foundation and the Fleischman Foundation.

MATERIAL AND METHODS

Subjects.—A total of seventy-three persons with endemic pellagra were studied at the Cincinnati General Hospital and at the Hillman Hospital of Birmingham, Ala. This number included all adults with classic pellagra admitted to either hospital between Dec. 15, 1937, and June 1, 1938. Forty-six had endemic pellagra; in sixteen pellagra developed after malnutrition resulting from other diseases, and in eleven it developed after chronic alcoholic addiction. All persons in this series had lesions of the mucous membrane diagnostic of pellagra; and fifty-six had characteristic pellagrous dermatitis. They all had lost weight, strength and appetite; fifty-one had mental symptoms, forty diarrhea, twenty-seven urethritis, twenty-four severe vomiting, twenty-three peripheral neuritis, twenty-three vaginitis, twenty-one proctitis, ten constipation and two cardiac decompensation (thought to be of the nutritional type described by Weiss and Wilkins³).

Observations on the children in several hundred "pellagra families" revealed that many of these children show clinical signs of early pellagra, and it therefore seemed advisable to include them in our studies. Preliminary studies indicate that the early symptoms are even more vague and difficult to recognize in the child than in the adult. The children are usually below normal in weight and height; they have made poor progress in school; they react sluggishly, and their inability to concentrate is easily noticeable. Poor appetite, indigestion, vomiting, soreness of the tongue and lips and constipation are common symptoms.

A dietary history of the family reveals that in many cases the diet of the mother during pregnancy was inadequate and that shortly after birth the child was given a formula because the mother had insufficient milk. This formula was not always adequate in the essential nutrients. Frequently the child has been a "feeding problem" since birth, refusing to take enough of the formula for his energy needs and later showing a preference for one or two foods and refusing all others. The diet has consisted almost entirely of carbohydrate foods; milk, eggs and meat either were not included or were given in insufficient quantities.

Thirty-six of the children observed had glossitis and dermatitis diagnostic of pellagra. After the administration of nicotinic acid (from 100 to 200 mg. daily) or one of its compounds, they experienced an increased sense of well being and disappearance of symptoms. Ten children without the usual diagnostic evidence of pellagra gave a similar response after the ingestion of nicotinic acid.

We interpret these observations as indicating that a slowly progressing deficiency in the antipellagra factor commonly existed in the children studied but that definite diagnostic evidence of pellagra develops late.

In addition to these patients, 199 with subclinical pellagra were studied at the Hillman Hospital. Further study of some of the reactions already noted in pellagrins following oral or parenteral administration of nicotinic acid was carried out on 100 normal adults at the two hospitals.

Method of Study.—As soon as the pellagrin in severe relapse came to either hospital, he was placed under the direct charge of one of us, who assumed responsibility for thorough clinical studies, for all indicated laboratory determinations and for therapy and

3. Weiss, Soma, and Wilkins, R. W.: The Nature of the Cardiovascular Disturbances in Nutritional Deficiency States (Beriberi), *Ann. Int. Med.* 11:104 (July) 1937.

necessary control measures. We were given invaluable assistance by the professional and administrative staffs of both hospitals and particularly by Dr. James B. McLester; Miss Jean Grant, dietitian; Miss Ann Van Blaricom, nurse; Miss Elizabeth Zschiesche, Miss Nelwyn Huff and Miss Helen Grant, technicians, and Dr. Yasuo Sasaki, E. S. Gross and S. P. Vilter, chemists. The method of study in general was similar to that previously adopted for determination of the presence of an antipellagra factor.⁴ This method may be described briefly as follows: If the lesions of the mucous membranes of a pellagrin show no improvement over a period of several days while the patient's diet is restricted, they serve as an effective index for testing the potency of a potential therapeutic agent. If the substance has therapeutic value, the lesions will heal promptly when sufficient amounts of the substance are added as a supplement to the diet, all other conditions remaining constant. Repeated determinations of nicotinic acid and porphyrins in the urine were made before, during and after the period of treatment. These determinations will be reported later. Repeated smears of the lesions of Vincent's infection were made before, during and after treatment.

Dietary Management.—The seventy-three pellagrins were divided into four groups. Each subject was observed during a control period of from one to three days. The first group consisted of twenty-two pellagrins who drank water but ate no food during the test period; the second group was composed of twenty-one pellagrins who received from 100 to 200 Gm. of dextrose daily and drank water ad libitum during the control period; the third group consisted of fourteen pellagrins who were offered an ordinary hospital diet and water ad libitum (these patients refused to eat more than small amounts of food, and their lesions failed to improve); the fourth group consisted of the remaining sixteen pellagrins, who were given only a basic diet and water ad libitum for a period of from two to three days. At the end of the control period, nicotinic acid or a similar drug was given to each patient. After improvement occurred, every patient was given a well balanced, high vitamin diet.

Materials and Mode of Administration.—The nicotinic acid employed in the treatment of the pellagrins in this series was supplied by the Eastman Kodak Company, Harris Laboratories, Merck & Co., the S. M. A. Corporation, Mead Johnson & Co. and Abbott Laboratories. Synthetic nicotinic acid amide was given to two patients, and sodium nicotinate, supplied through Merck & Co., was given to five. Coramine, furnished by Ciba Pharmaceutical Products, Inc., was given in doses of from 4 to 20 cc. daily to eleven pellagrins. Some of the patients given nicotinic acid amide or coramine, after showing the same clinical response as the other patients, were later given maintenance doses of nicotinic acid. Two patients were given a total of 1 and 1.5 Gm. of trigonelline, respectively, but there was no improvement; they were then given the same amount of nicotinic acid and responded promptly.^{4a} Only two of the pellagrins

in this series were treated by intravenous injections of nicotinic acid, as we had shown previously that the oral method of administration is highly satisfactory. One of these patients received 10 mg. and the other 20 mg. daily for a period of four days. The oral dose of nicotinic acid and of the salts used in this study varied from a daily total of 50 mg. to 1 Gm. The individual oral dose usually varied from 20 mg. to 500 mg. We preferred to use amounts of from 50 to 100 mg., given five or six times daily. Each patient was observed carefully after the administration of any of these substances, and the pulse rate, temperature and respiratory rate were determined. Also, the patients were questioned concerning any untoward sensations, and laboratory studies were frequently made, which included blood counts, tests of the blood chemistry such as determination of the carbon dioxide-combining power, electrocardiograms, and roentgen examinations.

OBSERVATIONS

Within seventy-two hours of administration of large amounts of nicotinic acid, sodium nicotinate, nicotinic acid amide or coramine to the seventy-three pellagrins, we regularly observed fading of the mucous membrane lesions, blanching of the erythema of the cutaneous lesions when present, a tendency toward the return of normal gastrointestinal function, remission of mental abnormalities when they were present and a decrease or cessation of porphyrinuria. (Two of the patients died subsequently, one from uremia and the other from obstruction of the esophagus associated with the mediastinal lymphadenopathy of Hodgkin's disease.) Soon after receiving any one of these substances, the pellagrin volunteered that he felt a sense of general well being and manifested much more interest in his disease and in conditions around him. Within the first twenty-four hours the picture of apathy and lassitude gave way to one of wide-awake interest. Likewise, the effect of nicotinic acid or one of its compounds on the alimentary tract was dramatic. Usually within twenty-four hours, sometimes a day later, there were striking objective changes in the mucosa of the mouth, throat and tongue, and in the rectum. The abnormal redness and the Vincent's infection disappeared. The appetite of some of the patients increased and the stools rapidly became normal, irrespective of whether the person had diarrhea or suffered from constipation. The amount of porphyrin in the urine, which was increased in forty-six of the forty-eight pellagrins tested, returned to normal after the administration of adequate amounts of nicotinic acid or one of its salts. The two pellagrins without increased porphyrinuria had extensive lesions of more than three months' duration. The fiery red dermal erythema of all patients blanched after the administration of nicotinic acid, but we did not note any special healing effect on the dermatitis of patients in whom the continuity of the skin had become broken and whose lesions were moist and ulcerated or dry and thickened. The vaginitis and urethritis usually disappeared within the first twenty-four hours. The two patients with cardiac decompensation showed a decrease in dyspnea, orthopnea and edema in three and four days, respectively, after the oral administration of 500 mg. of nicotinic acid and the injection of from 40 to 100 mg. of thiamin chloride (crystalline vitamin B₁ hydrochloride) daily. The peripheral neuritis present in ten of the patients was not relieved by nicotinic acid, but the pain and numbness disappeared within forty-eight hours after the injection of 50 mg. of vitamin B₁ twice

4. Spies, T. D.: Pellagra: Improvement While Taking So-Called "Pellagra-Producing" Diet, *Am. J. M. Sc.* 184: 837 (Dec.) 1932; Observations on the Treatment of Pellagra, *J. Clin. Investigation* 13: 807 (Sept.) 1934.

4a. Through the cooperation of Dr. M. K. Heath, Dr. K. U. Jones, and Dr. J. M. Bryan, veterinarians of Birmingham, Ala., nicotinic acid, nicotinic acid amide, sodium nicotinate and coramine have been used in the treatment of forty cases of spontaneous canine blacktongue. In these cases there was no dermatitis; there were no mental symptoms, and no evidence of increased porphyrinuria was produced by the method of Beckh, Ellinger and Spies. In every instance there was spectacular improvement within twenty-four to forty-eight hours.

each day. This finding has been reported in detail by Spies and Aring.⁵ Perhaps the most striking improvements following the administration of nicotinic acid to a pellagrin in relapse are the change in mood and personality, and the disappearance of mental symptoms. Since these changes are unusually difficult to describe, two representative case histories from those of the eighteen patients with unusually severe pellagrous psychoses are given in some detail:

CASE 1.—History.—I. C., a Negro widow, aged 59, had a progressive illness of at least nine months' duration. The family history and the past history are irrelevant.

About a year before admission the patient became weak and complained of vague discomfort in the epigastrium following meals, of gaseous eructations, anorexia, nausea on occasion, constipation and of weakness. She lost 15 pounds (6.8 Kg.) within the next three months. Thereafter the symptoms became progressively worse. During the two months just prior to admission to the hospital, she had little food; spent all her time in bed because of weakness; complained of soreness, particularly in the substernal region; lacked interest in her household, and did not observe her surroundings. Her memory became impaired, and she became disoriented and had hallucinations. Her family said that she didn't notice the things which she had formerly, that she often complained of seeing snakes and worms, and that she was "crazy and foolish in the head." Her food during the course of her illness consisted of decreasing quantities of turnip greens, rice, bread, syrup and milk.

Physical examination showed an emaciated Negress who appeared to be acutely and chronically ill. She had swelling and reddening of the mucous membranes of the tongue, mouth, throat and vagina. She had characteristic lesions of pellagra over the nose, forehead, dorsum of the hands, wrists, elbows, knees and feet. The tendon reflexes were equal and hyperactive. All coordinating movements were jerky. She was somnolent and depressed. When aroused, she was always confused and apprehensive, refused to cooperate and was disoriented as to time and place. Her memory was impaired so that she could not recall the trip from her home to the hospital or the names of her children.

The laboratory examinations gave essentially normal results except that the hemoglobin content was 58 per cent, the red blood cell count was 2,900,000 and large amounts of coproporphyrin were found on repeated tests of the urine.

Course in the Hospital.—During the first three days in the hospital she resisted attention, would not take food and remained depressed mentally. She was given nicotinic acid by force in doses of 1,100 mg. during the first twenty-four hours and 500 mg. daily thereafter. After twenty-four hours of treatment, definite improvement of the mucous membranes was noted, and by the third day they appeared normal. On the fourth day she was less depressed mentally and less confused and willingly took food and medication. On the fifth day she talked freely, conversed with other patients, became interested in her condition and apparently had insight for the first time into her illness. She volunteered that she had been "crazy in her head" and that she did not know anything about coming to the hospital. She stated that she had thought that snakes, worms and knives were crawling over her but that she now realized that these sensations were unreal. Her appetite and general condition improved and she was discharged from the hospital in good condition.

CASE 2.—E. B., a Negress aged 49, was admitted to the hospital because of severe pellagra. The family history and the past history are irrelevant.

For almost a year the patient had eaten chiefly sweet and greasy foods and occasionally some green vegetables. About three months prior to admission extreme anorexia developed and she lost weight. She felt weak, experienced abdominal discomfort and noticed alternating periods of diarrhea and of constipation. She often had involuntary defecation and urination, became unable to sleep, was very nervous and, according to her

family, had severe personality changes. A severe "hurting in the stomach and breaking out of the skin" developed one month before admission. During the last two weeks before coming to the hospital she was unable to get out of bed and refused all food. She was unable to sleep, her memory was impaired and she was disoriented entirely as to time and place. She had hallucinations characterized by the seeing of insects and snakes, and thought that people were trying to poison her; she heard groups of people discussing attempts to kill her. She had many delusions of persecution.

The patient was emaciated, confused and restless, and she required restraint. The mucous membranes of the tongue, mouth, throat, gums and vagina were red, and small areas of ulceration were present. The skin in general was dry, rough and loose. She had sandpaper-like roughness over the nose and forehead and pellagrous dermatitis over the neck, bony prominences, dorsum of the hands, wrists, forearms, feet, ankles and perineum. Many of the lesions were thickened and pigmented, excoriated and macerated. A decubitus ulcer was present over the sacrum. All tendon reflexes were present and hyperactive. Her mental status was one of confusion, apprehension, restlessness and disorientation as to time and place. She had delusional ideas of persecution and visual and auditory hallucinations.

Laboratory work gave essentially normal results except that the blood hemoglobin content was 70 per cent and the red blood cell count 3,700,000.

Course in the Hospital.—During the first ten days, while the patient was taking a basic diet and no medication, except 3 ounces (90 Gm.) of brewers' yeast on the first day, her condition remained stationary. There was slight healing of the skin during this period. During the next twelve days she was offered but took little of a high caloric, high vitamin diet, and each day she received four injections of 10 cc. of liver extract. During this period there was progressive healing of the dermal lesions and the tongue became normal. She took little food, and there was no essential change in the mental condition. Involuntary defecation and urination continued. On the twenty-second day in the hospital the administration of nicotinic acid was begun in doses of 100 mg. five times a day. Three days later she was mentally clear and cheerful, talked freely and had no delusions or hallucinations. She began to eat more. On the fourth day she ate all the food on her tray and on the fifth day asked for and ate a second regular hospital tray of food. One week after the treatment by means of nicotinic acid she became inquisitive about being brought to the hospital and about members of her family. She was discharged from the hospital in good condition.

THE EFFECT OF NICOTINIC ACID ON SUBCLINICAL PELLAGRA

Having found that nicotinic acid is effective in treating pellagra and in preventing recurrences under hospital conditions,⁶ we thought it worth while to study its effect on adult pellagrins living at home without change in environment or activities. One hundred and ninety-nine such pellagrins who were subject to one or two recurrences of the disease each year were selected for study.

Within one to three days after treatment with nicotinic acid was instituted, nearly all the patients volunteered that they felt much better and that dizziness, depression, burning sensations, confusion and "upset head" had disappeared. Thirty of the patients who had suffered from chronic constipation stated of their own accord that their bowel movements returned to normal after they took nicotinic acid. One patient whose pellagra had been complicated by mucous colitis had normal stools for the first time in three years.

After continuing to take the prescribed amount for several weeks, however, many of the patients stated

5. Spies, T. D., and Aring, C. D.: The Effect of Vitamin B₃ on the Peripheral Neuritis of Pellagra, *J. A. M. A.* 110: 1031 (April 2) 1938.

6. Grant, J. M.; Zschiesche, Elisabeth, and Spies, T. D.: The Effect of Nicotinic Acid on Pellagrins Maintained on a Pellagra-Producing Diet, *Lancet* 1: 939 (April 23) 1938.

that they did not feel especially well. The dose of nicotinic acid was increased in such instances and this was invariably followed by a second improvement in sense of well being and increase in energy. In a group of control patients these periods of improvement have not occurred. These studies are still in progress and will be reported later,⁷ but we can say that the pellagrins in the test group, as contrasted with those in the control group, have been benefited and that nicotinic acid is valuable in preventing recurrences of pellagra. It is of interest that in a number of cases evidence of vitamin B₁ deficiency developed while the patient was taking large quantities of nicotinic acid.

Throughout all the studies we observed that the response of the individual pellagrin to a given amount of nicotinic acid, or to one of its salts, is extremely variable. For example, we have noticed healing after the administration of as little as 40 mg. of nicotinic acid daily by mouth in one person, while in other persons receiving the same amount the disease became worse. We have given a single oral dose of 1 Gm., which produced transient flushing, reddening and burning of the skin, followed by remission of the pellagrous lesions. We do not, however, recommend such large doses, as the subsequent symptoms are unpleasant and the results may prove to be deleterious in effect. Two patients who were restricted to a basal diet were given nicotinic acid intravenously because of their unwillingness to take the material orally. One of them showed improvement of the pellagrous glossitis and stomatitis and cessation of diarrhea after only 10 mg. had been injected daily for four days, while the other showed a prompt cessation of nausea and vomiting and healing of pellagrous glossitis after the daily administration of 20 mg. for the same length of time. Both of these patients were in the basal state, ate the full diet and had only mild lesions of pellagra. We have given single intravenous doses of 25 mg. in a 1:1,000 solution within two to three minutes without harmful effects, but we do not recommend that this dose of the material be administered so rapidly.

Although the symptoms of all pellagrins receiving nicotinic acid improved, irrespective of whether the patient was restricted to water, to water and dextrose or to a basic diet, we observed that the patients responded better if they ate large amounts of a well balanced diet, were kept at rest and had no coexisting disease.

EFFECTS OF NICOTINIC ACID ON 100 ADULTS WITHOUT PELLAGRA

In view of the fact that pellagrins in relapse and with subclinical pellagra often had flushing, burning and itching of the skin and other unpleasant symptoms after the administration of large amounts of nicotinic acid or its salts, it seemed essential to study this reaction in some detail in normal persons in order to ascertain whether the pellagrin had a peculiar reaction to these chemical substances.

Cutaneous Response.—The oral administration of large quantities of nicotinic acid is followed by flushing, burning, itching and an increased sensation of local heat in the skin. This finding apparently can be produced in all persons, although the amount required to produce it is extremely variable at different times in the same person and from one person to another. A patient with pellagra seems less likely to have this type of reaction. It was produced in about 5 per cent of the group when

an oral dose as small as 50 mg. in aqueous solution was given with the stomach empty, and it was produced in about 50 per cent when 100 mg. was given. It was present to some degree in every person receiving as much as 500 mg. orally, and the majority of the subjects had a reaction when 200 mg. was given. By detailed study of the changes in cutaneous temperature, we found that the increase was most marked over the ears, face and neck, less pronounced over the trunk and least pronounced over the extremities. In some cases the hands and feet showed no change, and occasionally they showed a decrease in temperature of from 1 to 2 degrees C. (1.8 or 3.6 degrees F.). Actual measurement of the changes in temperature by means of a thermocouple and a room with constant temperature (20 C.) revealed an average increase of from 1.5 to 2 degrees C. (2.7 to 3.6 degrees F.) over the face and neck (chart 1) and an increase of from 0.5 to 1 degree C. (0.9 to 1.8 degree F.) over the trunk. This elevation in temperature was most pronounced in areas where the other objective and subjective changes were present. The distribution of the changes followed the normal pattern of the cutaneous temperature, the temperature being greatest where the skin normally is warmest and

Fig. 1.—Changes in the temperature of the face (average of ten areas) of a normal man after oral administration of 100 mg. of nicotinic acid.

decreasing as it approached the colder periphery. The redness and flushing were extreme in the ears and striking over the malar bones, face and neck; they frequently assumed a blotchy and irregular distribution over the trunk and tended to decrease over the abdomen and the extremities. Occasionally, circumoral pallor was noted. In patients with the extreme degree of flushing there was sometimes slight elevation of the red areas. In some instances we noted flushing accentuated in the perineal and axillary regions, associated with a sense of increased warmth or itching. No change was noted in the tongue or mucous membranes. In a small percentage of the cases there was sweating, especially of the face and axillas. Usually the skin appeared more shiny after the flushing reaction.

Similar effects were observed following the intravenous injection of from 5 to 25 mg. of nicotinic acid in physiologic solution of sodium chloride. Variation in the pH from 3.4 to more than 7 did not change these effects.

Since the flushing, nausea, vomiting and abdominal cramps which sometimes follow the administration of large doses of nicotinic acid suggested a parasympathetic-like action similar to that produced by the

7. Spies, T. D.; Mc Lester, J. B.; Stone, R. E., and Grant, J. M.: Unpublished observations.

acetylcholine group of chemicals, it seemed advisable to make a comparative test for nicotinic acid and for acetylcholine. Chart 2 shows that the reactions produced by intra-arterial injection of acetylcholine and those produced by nicotinic acid are not identical. The nicotinic acid continues to give some general effect, demonstrating that it is not destroyed entirely or inactivated in the capillaries as is acetylcholine.⁸ In both cases there was an increase in cutaneous temperature of from 1 to 2 degrees C. in the leg which received the injection. Nicotinic acid has caused a reaction like that to histamine when intracutaneous injections were made. It was noted, however, that the wheals differed considerably from the typical histamine wheal. The local reactions from nicotinic acid occur less frequently, are less marked and are of shorter duration than are those from histamine. The associated pruritus is less severe than that caused by comparable amounts of histamine.

Cardiovascular and Respiratory Reactions.—No constant deviation in the pulse, blood pressure or respirations occurred after oral or intravenous administration

Fig. 2.—Temperature of the face (average of ten areas) of a normal man before and after injection of 10 mg. of nicotinic acid and 30 mg. of acetylcholine into the femoral artery.

of the drug under the conditions of this study. Rarely after intravenous injection of from 10 to 20 mg. of a 1:1,000 solution, given within a period of from one to three minutes, there was an increase in pulse rate of from five to ten beats per minute. This was not produced by similar injections of physiologic solution of sodium chloride. We have seen occasionally a transient increase in the rate and depth of respiration and in one patient true angor animi. Preliminary investigations with seven normal subjects revealed that there is no uniform variation in oxygen consumption during the period when the flushing is marked, but in two subjects there was some increase. We found no changes in the complexes in the electrocardiograms of four normal males made during or after the intravenous or oral administration of nicotinic acid in doses which produced the flushing reaction. Some patients have complained of dizziness after the oral administration of large doses.

Effects on the Gastrointestinal Tract.—Several subjects have complained of nausea and cramps in the epigastrium after the administration of single doses of nicotinic acid ranging from 300 to 1,500 mg. given orally and from 10 to 25 mg. given intravenously. Two

had vomiting; cramps and belching occurred in nine after the intravenous injection but in only four after the oral administration. In almost every instance the cramps occurred when the material was administered while the stomach was empty. Eight subjects were examined under the fluoroscope with barium sulfate in the stomach, before, during and after intravenous administration of the substance. No change could be demonstrated in four, but the other four had a definite increase in the depth of the peristaltic contraction rings of the stomach. Two of these four had severe cramps associated with generalized increase in gastric tonus, considerable decrease in the size of the stomach and complete cessation of all gastric movement for a minute. After resumption of gastric activity, the contraction waves rose much higher toward the cardiac end and were much deeper than they were prior to the administration of the drug. The subcutaneous injection of 5 mg. of nicotinic acid was followed in three patients by increased secretion of gastric hydrochloric acid, in one patient even when fasting anacidity was present. The magnitude of change, however, was not as large as that produced by 1 mg. of histamine in the same patient. Similar observations were made by V. P. Sydenstricker.⁹

Other Observations.—Because of the clearcut action of nicotinic acid on gastrointestinal function in pellagrins and in normal persons, we have made preliminary studies on a group of patients with constipation but without pellagra or organic gastrointestinal disease. In some instances there has been a striking return of bowel function to normal. In others, there has been no change.

In seven cases of radiation sickness we have used nicotinic acid orally in divided doses totaling from 200 to 1,000 mg. daily and have noted prompt cessation of the nausea, vomiting, anorexia and headache. In five of the seven cases the amount of porphyrin in the urine, which was abnormally large, returned to normal. Communications from V. P. Sydenstricker and John W. Spies indicated that they had observed similar results.

Since in dogs part of the nicotinic acid excreted in the urine is in the form of a conjugate with aminoacetic acid (glycine), nicotinic acid,¹ we have made a study of the reactions of flushing and temperature in normal persons who were given 30 Gm. of aminoacetic acid one hour before they were given 500 mg. of nicotinic acid orally. In six cases studied to date we found that the elevation of temperature was delayed and decreased when compared with the elevation in control tests, in which aminoacetic acid was not given. Because we have found that the quantitative estimation of change in temperature after the administration of nicotinic acid varies considerably in a given person under standard conditions with the same dose, we have not yet enough data to be certain that this effect with glycine was not fortuitous.

Excretion of Nicotinic Acid of Pellagrins in Relapse, of Persons with Subclinical Pellagra and of Normal Adults.—Since some persons given the drug complained of increased frequency of urination after taking nicotinic acid, five subjects were given a constant fluid intake, with the output measured, for a week and were then given a total of 750 mg. of the drug orally in five equal, hourly doses. The urinary output was measured, and it was found that there was a slight increase during the period immediately following ingestion of the drug but

8. Ellis, L. B., and Weiss, Soma: A Study of the Cardiovascular Responses in Man to the Intravenous and Intra-Arterial Injection of Acetylcholine, *J. Pharmacol. & Exper. Therap.* 44: 235 (Feb.) 1932.

9. Sydenstricker, V. P.: Personal communication to the authors.

that there was no significant change in the twenty-four hour output for the control period and for the subsequent three days. It was found also that there was no significant change in the carbon dioxide combining-power of the blood after administration of this quantity of nicotinic acid. When doses of from 10 to 25 mg. of nicotinic acid were given intravenously, the substance appeared in increased amounts in the urine within the first hour. In some cases the content would not return to the preinjection level for one or more hours. When smaller doses, 10 mg. or less, were given, the nicotinic acid returned to the control level within one hour. Oral doses of 20 mg. or more usually did not produce a maximal rise in the content in the urine until the second, third or fourth hours.

Comparative study of several hundred determinations of nicotinic acid in the urine suggests a tremendous variation from time to time in the individual person and from person to person, but there does seem to be some influence on the amount excreted, depending on whether a person has a normal supply in his diet, on the amount of the drug given and on the mode of administration. Also, the evidence suggests that the body of a pellagrin in relapse retains more of the drug when it is administered than does a normal person of the same size, and that the flushing reaction is less frequent and less intense in the severely ill pellagrin than in the normal person given the same amount.

COMMENT

Study on the response to the nicotinic acid group of chemicals in the seventy-three pellagrins in relapse and in the persons with subclinical pellagra suggest that these substances are essential for the proper nourishment of the cells. Analysis of the case histories of several hundred pellagrins in relapse shows that three factors may operate to produce a deficiency of these substances in human beings: 1. The intake of foods containing nicotinic acid may be inadequate. 2. The absorption of nicotinic acid may be below normal because of some altered gastrointestinal function. 3. The intake may be sufficient and absorption normal for the average person, but there may be an increased demand because of excessive exercise, insomnia, hyperthyroidism or other conditions which increase the body's need.

The role of nicotinic acid in the nutrition of the body is not clear. It appears however that, if the body lacks adequate amounts of this substance or substances that act similarly, ill health occurs and pellagra eventually may develop. Studies on nicotinic acid have been so meager that its precise effect on the cells of the body is not known. The present observations, however, show that its lack leads to cellular alteration in the alimentary tract, skin and other systems, and to alteration in porphyrin metabolism. That nicotinic acid has a fundamental role in porphyrin metabolism is suggested by the fact that not only the porphyrinuria of pellagra but also that of other diseases has been decreased after the administration of nicotinic acid.¹⁰ The observations that two normal adults ingesting a diet deficient in nicotinic acid showed increased porphyrinuria within a week and that the increased porphyrinuria disappeared after the administration of this substance also indicate a close interrelationship between nicotinic acid and por-

phyrins.¹¹ Certain observations suggest that, in addition to playing an apparently fundamental part in porphyrin metabolism, nicotinic acid is necessary for the normal functioning of the gastrointestinal tract.

For some time investigators have thought that pellagra may be due to a deficiency of more than one essential nutritional substance. Aring and Spies⁶ recently showed that nicotinic acid will not relieve the pain and numbness caused by the peripheral neuritis of pellagra, whereas these symptoms can be relieved promptly by the administration of thiamin chloride. Conversely, these investigators have shown that the mucous membrane lesions of pellagra, which are cured by nicotinic acid, are not affected specifically by thiamin.

The present study reveals that the mild mental symptoms, consisting of confusion, dizziness, loss of memory and depression, are promptly benefited by nicotinic acid and that even the severe psychoses often associated with pellagra will be relieved by the administration of this substance. One patient who showed no clinical evidence of pellagra but who had had diarrhea for about twenty-five years and who, during the past few months, had acquired a severe psychosis in which she became disoriented as to time, place and person, responded rapidly and dramatically to the administration of nicotinic acid. Studies now being carried out on the prevention of recurrences of pellagra by means of nicotinic acid show to date that recurrences are at least delayed by the administration of this substance.

Despite the evidence presented in this paper showing the beneficial effects of nicotinic acid in the treatment of pellagra, we are convinced that all patients with pellagra should be given sufficient rest, adequate amounts of a well balanced diet, appropriate treatment for coexistent diseases and palliative therapy when necessary.

SUMMARY AND CONCLUSIONS

1. The present report confirms the previous observations of Spies, Cooper and Blankenhorn that after adequate doses of nicotinic acid, nicotinic acid amide or sodium nicotinate the pellagrous glossitis, stomatitis, vaginitis, urethritis and proctitis are healed; that the early erythematous lesions of pellagra are blanched, and that the porphyrin content of the urine returns to normal. In addition it has been found that the diethyl amide of nicotinic acid (coramine) has somewhat similar therapeutic properties, whereas trigonelline, in comparable doses, is inactive.

2. The present studies show that the early and late mental symptoms of pellagra in relapse and of subclinical pellagra are benefited dramatically by the administration of nicotinic acid. These results strongly suggest that nicotinic acid or closely related substances are essential to the integrity of the cells of the body, and that a sufficiently prolonged deficiency of such substances results in ill health and eventually in pellagra. To us it seems that pellagra should be considered as a reaction of the body to lack of essential nutritional substances and not just as a dermatitis, and that nicotinic acid is one of those essential substances and is necessary for the normal functioning of the gastrointestinal tract, the skin, the nervous system and probably other systems. It is of interest that the pellagrins who had associated Vincent's infection, mucous colitis, constipation or diarrhea were relieved of these conditions after the ingestion of nicotinic acid. In a group of patients

10. Spies, T. D.; Gross, E. S., and Sasaki, Y.: Effect of Yeast and Nicotinic Acid on Porphyrinuria, *Proc. Soc. Exper. Biol. & Med.* 38: 178, 1938.

11. Spies, T. D.: Unpublished observations.

without pellagra but with constipation, bowel function frequently resumed a normal status after oral doses of nicotinic acid. In some cases, however, there was no improvement.

3. Relapse in 199 patients with subclinical pellagra (who had previously had one or two recurrences each year) has been prevented through the "pellagra season" by daily oral doses of nicotinic acid. In some of these patients vitamin B₁ deficiency developed.

4. A study of the children in several hundred "pellagra families" indicated that a slowly progressing deficiency in the antipellagra factor commonly exists in these children but that definite diagnostic evidence of pellagra develops later. After the administration of nicotinic acid or one of its compounds they experienced an increased sense of well being and disappearance of symptoms. Pellagra in thirty-six of the children having the manifestations of acute pellagra responded to the oral administration of ten doses of 10 mg. each per day of nicotinic acid in the same manner as in adults.

5. The oral method of administration of nicotinic acid, nicotinic acid amide or sodium nicotinate is recommended except for patients unable to ingest the material by this route. The giving of nicotinic acid in oral doses of 200 mg. or in intravenous doses of 10 mg. within one minute nearly always produces dilatation of the small vessels of the skin of the face and the upper part of the trunk. This is characterized by increased temperature, flushing, burning and itching sensations. The sebaceous glands take on increased activity. Gastrointestinal motility may be increased, particularly if the drug is administered when the patient's stomach is empty. The pulse, blood pressure and respirations and the electrocardiogram are not regularly changed. The drug has a weak reaction like that to histamine and is not destroyed by passage through the capillaries, as is acetylcholine.

6. Observations on these pellagrins and on normal persons indicate that the requirement for nicotinic acid, nicotinic acid amide, sodium nicotinate or the diethyl amide of nicotinic acid is increased by infection, physical exercise and elevation of temperature. The dose of nicotinic acid and of these compounds required for any given pellagrin is extremely variable, but 500 mg. a day in divided doses is usually effective. Smaller doses, however, often produce dramatic relief of symptoms. In some cases twice this amount seemed more effective. It is recommended that all patients in relapse and those having subclinical pellagra be given a well balanced diet, ample rest in bed and effective treatment for any coexisting disease even when nicotinic acid is used as a supplement.

ABSTRACT OF DISCUSSION

DR. THOMAS T. MACKIE, New York: The authors have made a most important contribution in their confirmation of the amazing therapeutic value of nicotinic acid in the treatment of pellagra. There are three points that I should like to discuss. I have been interested in secondary deficiency disease for years. The lesions of the tongue described as the early indication of pellagra do not differ from similar lesions seen in persons in New York City who are suffering from mixed deficiency states and in whom the characteristic lesions of the skin never develop. In the second place, there is the matter of definition: What are the criteria which justify the diagnosis of pellagra? Like dropsical sprue and nondropsical sprue, pellagra is a clinical entity, and by definition it is associated with the appearance of the tongue and buccal mucous membrane, symmetrically disposed dermatitis and lesions and disturbances of the central nervous system. It is important for the time being

to hold strictly to these criteria. It is interesting, in looking back through the recent developments of medicine, to see how some new bit of knowledge is applied by different people in different parts of the world at almost the same time. The use of nicotinic acid in the treatment of pellagra is no exception to this. Elvin and his associates used nicotinic acid in the control of canine blacktongue. In November 1937 Foots and his associates first reported the use of this preparation for human pellagra. In December 1937 Smith and Ruffin reported the use of nicotinic acid in the treatment of a human being with pellagra. Finally, Dr. Spies and his associates brought out their first and exceedingly important contribution in February of this year. Another point I should like to make is the necessity for caution in the interpretation of the value of nicotinic acid for so-called pellagra, at least as it is seen in the North, where it occurs almost invariably as the result of alcoholism or some advanced and serious chronic disease. In that respect it differs materially from the true endemic pellagra of the South. It seems not unreasonable, therefore, to anticipate that the therapeutic value of nicotinic acid in the hands of practitioners may appear to be less effective in the North than in the South. It has been my experience that the drug should be used with caution in treating patients presenting the lesion of the tongue which the authors described but not the lesions of the skin and that the drug is not as effective as it appears to be for the true endemic pellagra.

DR. JULIAN M. RUFFIN, Durham, N. C.: For the critical evaluation of the potency of any therapy, definite criteria must be established. With pernicious anemia, for example, one uses the rise in the reticulocytes. In pellagra there is no one symptom or sign the subsidence of which can be taken as conclusive evidence of remission. It is well recognized that the dermatitis may fade spontaneously when the patient is protected from the direct rays of the sun and that the patient may actually die after the dermatitis has disappeared. Therefore the subsidence of the dermatitis cannot be taken as satisfactory evidence of remission. Glossitis is a common symptom in pellagra. The authors apparently have accepted subsidence of the glossitis within a few days as evidence of the potency of the drug used. According to my experience this conclusion is not justified. Spontaneous subsidence of the glossitis occurred in twenty-six of seventy-two cases of pellagra (36 per cent). Furthermore, the glossitis recurred in sixteen of these cases after exposure of an arm or leg to the direct sunshine. I feel, therefore, that subsidence of the glossitis per se cannot be taken as conclusive evidence of remission. Improvement in the patient's general well-being, associated with subsidence of the dermatitis, glossitis, diarrhea and dementia, if present, and absence of relapse after exposure to sunshine constitute the only conclusive evidence of remission. However, since many other deficiencies result in a picture similar to that seen in pellagra, I feel it extremely unwise to make the diagnosis of pellagra or even of subclinical pellagra in the absence of a characteristic rash or a reliable history of one. I have found that small doses of nicotinic acid (1.5 mg. per kilogram of body weight, from 70 to 100 mg. daily) result in prompt recovery and are as effective as doses ten times as large in the average case of acute pellagra or for blacktongue. Large doses of nicotinic acid, 1 Gm. daily, invariably result in unpleasant sensations. Ten students were given 1 Gm. a day, divided into four doses. In every case flushing of the face and neck occurred. In two cases nausea and vomiting developed. One student was quite ill for twenty-four hours. In two cases marked cyanosis of the finger nails developed and disappeared at the end of twenty-four hours. Furthermore, Dr. Chen has reported that the daily administration of 2 Gm. of nicotinic acid to two dogs over a period of twenty days resulted in the death of both dogs. It should be emphasized, therefore, that the drug is definitely toxic, and the indiscriminate use of large doses is to be deplored.

DR. MOHAMMED ABDO ABBASY, Cairo, Egypt: It is a great privilege to be allowed to speak before such a learned gathering. I feel highly honored and thankful for the circumstances that brought me to San Francisco during this time. Egypt is concerned with the question of pellagra and its treatment with nicotinic acid. The work published by Dr. Harris in England,

Dec. 18, 1937, was in part done in Egypt by Professor Ali Hassan, and this work was arranged by the Nutritional Laboratory in Cambridge when I was working there with Dr. Harris. I am inclined to agree with Dr. Spies in considering pellagra a multiple deficiency disease. It is reasonable that the victims of pellagra miss many things in their diet other than nicotinic acid or one of its compounds. The fact that the peripheral neuritis responds only to a supplement of vitamin B₁ and that pellagrins responded to nicotinic acid better when they were receiving a well balanced diet is in favor of this view. It remains only for future investigation to disclose whether more substances are involved in pellagra and if so their role in the prevention and cure of the disease. The history of pellagra in Egypt is linked with the introduction of maize into the country. The first cases recorded appeared four or five years after the introduction of this crop. In Lower Egypt, where more maize is grown and consumed by the peasants than in Upper Egypt, owing to the different systems of irrigation in the two parts of the country, pellagra is more prevalent. Pellagra in Egypt is in the nature more of a secondary deficiency disease than of a primary one. Genuine pellagra does occur because of a lack in the diet of the factor or factors concerned. In a greater percentage of cases, however, it is due to lack of absorption of the factors concerned, although they are present in the diet, because of severe gastrointestinal disturbances caused by intestinal parasites, mainly *Schistosomum mansoni* and *Ancylostoma*. Members of one family, who are sharing their food and eating nearly the same quantities of it, are some of them victims of pellagra while the others are not. Those who are the victims are nearly always found to be heavily infested with intestinal parasites, and once they are freed from these parasites the pellagra is cured without any change in the diet. In Lower Egypt, where the perennial system of irrigation operates (and this system exposes the farmers much more to infection, with *Schistosomum mansoni* especially), schistosomiasis is more prevalent than in Upper Egypt, where the basin system of irrigation is generally adopted, and, as expected, pellagra also is more prevalent in Lower Egypt. Pellagra in Egypt is not confined to the poorer classes of the community as it is in the United States; it also has victims among the richer classes who are subject to the evils of these intestinal parasites.

DR. J. N. BAKER, Montgomery, Ala.: It was an Alabama physician, Dr. George H. Searcy, who first reported pellagra in endemic forms. His report, made in 1907, contributed notably to the study of the disease and had the highly beneficial effect of making not only the medical profession but the general public pellagra conscious. It told of the existence since 1901 of formerly unrecognized pellagra in the Mount Vernon (Ala.) insane asylum. Pellagra was responsible for 306 deaths in Alabama in 1936, divided almost equally between the white and the Negro races; a rather significant fact, since the white population outnumbers the Negro almost two to one. For the population as a whole the death rate for pellagra was 10.8 per hundred thousand. The rate for white people was 8.2 and for Negroes 15.4. A deficiency disease like pellagra can be expected to be more prevalent and more fatal in communities where standards of living are low, and the study of pellagra which has been mentioned emphasized this fact so far as this state is concerned. Some time ago the Tennessee Valley Authority made public the results of a study of spendable per capita income in several Southeastern states and also of per capita spendable income by counties within certain states. The statisticians found that the per capita spendable income of Alabama as a whole was \$214, which may appear low to persons from wealthy industrial states. Four of the thirteen counties having a death rate for pellagra of 15 per hundred thousand of population or higher were shown to have spendable incomes of less than \$100 a year. It is a medical axiom that death rates, both the general death rate and the rates for specific diseases, reflect at least in part the adequacy or inadequacy of medical care. Thus one would expect that the counties having an unusually high death rate for pellagra would have inadequate medical service. This is true so far as Alabama is concerned. Of the thirteen counties having an abnormally high death rate for pellagra, all but four actually have fewer

physicians than they had a quarter of a century ago. These four apparent exceptions to the rule are the counties already mentioned as having an unusually high per capita spendable income. Study has thus given added strength to the assumption that living standards, medical care and other physical factors play a vitally important part in the killing power of pellagra and that, contrary to a widely held belief, the death rate does not go up as a consequence of prosperity or come down as a consequence of economic distress.

DR. JAMES E. PAULLIN, Atlanta, Ga.: Since 1907 I have been interested in pellagra, for at that time there was a tremendous amount of it in the South. In attempts to confirm the existing theory as to the etiologic factor, it was soon found that maize had nothing to do with its prevalence. Since that time various efforts have been made to diagnose early pellagra and to institute proper treatment. I agree with the authors that dermatitis is not always necessary for a diagnosis of pellagra. Patients without any other evidence of pellagra may have the dermatitis, and there may be innumerable gastrointestinal and nervous symptoms that establish a diagnosis of pellagra without dermatitis and without its production on exposure to the sun. While the diagnosis may be a question for debate, there isn't any question about the beneficial results of nicotinic acid in patients who have pellagra without extensive dermatitis. The authors have not painted the dramatic improvement which will occur within twenty-four hours in a patient who is part of the time a bed and the remainder of the time on a bedpan and has a most intense, ulcerative, inflamed lesion of the mucous membranes of the mouth. In from twenty-four to forty-eight hours after the administration of nicotinic acid he is able to occupy the bed in comfort and is able to take nourishment and retain it; such a transformation is rather remarkable. Nicotinic acid does not produce rapid disappearance of the dermatitis, but with the discovery that this very useful drug overcomes the clinical syndrome this matters not so very much. The drug is a wonderful contribution to clinical medicine and to the health and comfort of many sufferers.

DR. A. J. CARLSON, Chicago: I have followed the problem of pellagra with a great deal of interest since the days of Goldberger. I want to ask one question and speak one word of caution. I am informed that in the Carolinas the Red Cross has for years supplied poor families with an abundance of yeast and that despite taking it (or presumably taking it) the families have periodic ups and downs with so-called pellagra. I wonder whether the authors have any explanation of this, assuming that the information is correct. This leads me to another point, the point of caution, hinted at by several of the discussers, particularly Dr. Abbasy. If pellagra is a deficiency disease and if nicotinic acid really cures any of the symptoms, nicotinic acid must be a food. Also one should not be too enthusiastic, in view of what is known regarding the deficiency in all other aspects of the diet of the people affected. Nicotinic acid, while it may relieve and cure suddenly some of the symptoms of pellagra, can probably not overcome a general dietary deficiency. So I think that in the long run nicotinic acid will not relieve either the medical profession or society of the necessity of looking for a more nearly optimum diet for the great portion of the population affected. It would be curious indeed if there was only one factor, namely nicotinic acid, in the pellagra complex. The physician may be deceiving himself if he thinks that the patient is all right when he has recovered from the acute stage with the aid of nicotinic acid. That is my word of caution. I do not think that Dr. Baker intended to say that the medical profession is responsible for pellagra in Alabama.

DR. J. N. BAKER: I think that the problem is one of economics.

DR. A. J. CARLSON: Not entirely. It may be a case of economics for people who live in the city and so have to buy every item of food. It is not a mere problem of economics in the case of people who have an acre of land, but not the sense to raise food on it.

DR. P. J. HANZLIK, San Francisco: I was glad to hear the discussion by Dr. Ruffin because it was the first time that

I have heard some caution expressed about the use of this agent. Pharmacologists know that a therapeutically useful agent is generally also toxic. Although nicotinic acid is far removed chemically from nicotine, the patients reacted with effects on the circulation, nausea and vomiting and other symptoms. This suggests that nicotinic acid shares some of the actions of nicotine. Apparently it is going to be used repeatedly, and it is a symptomatic remedy, at least at present. Whether it is a drug or something else makes no difference. It is being used extensively, however, and another word of caution, in addition to that of Dr. Carlson, therefore seems to be in order. I should like to suggest studies of the action of this agent over long periods, small and large doses being used and evidence of chronic intoxication being sought. What will the drug do under these conditions to the blood, to the viscera and so on? When nicotine is used in this way over long periods it is injurious. I offer the suggestion that nicotinic acid be used more cautiously than it appears to be, especially in view of the large doses that are employed.

DR. WILLIAM DEKLEINE, Washington, D. C.: Dr. Carlson mentioned the work of the American Red Cross. In the period from 1927 to 1934 the Red Cross distributed over a half million pounds of powdered yeast. The highest aggregate death rate for pellagra ever recorded in this country in the thirteen Southern states where the disease prevails most extensively occurred in 1928. After the distribution of a half million pounds of powdered yeast and the introduction of gardening the rate was gradually reduced until 1935, when it was 60 per cent below the 1928 rate. Dr. Baker said that pellagra is largely an economic problem. It is just that. The tenant farmers in the South buy their food at the corner grocery or commissary. They do not grow it on the farm. Gardening has until recently been a lost art on the cotton plantations of the South. It is coming back slowly, now that plantation owners and tenants have learned its value. The food purchased in the stores is the cheapest kind—fat meat, meal, molasses and so on—food that does not contain the pellagra-preventive factor. That is why the death rate for pellagra is so high. Until it is made possible for people to get the food they need pellagra will not disappear. Is it the opinion of Dr. Spies and his co-workers that nicotinic acid is the same as the pellagra-preventive factor of Goldberger? Judging from what Dr. Ruffin has said there is some doubt. In view of the importance of pure yeast as a control measure, is nicotinic acid equally effective and can it take the place of yeast, or must further experimentation be awaited? I am inclined to think that physicians should wait until they know more about its effects. Powdered yeast has not been distributed in recent years. I am wondering now whether it should again be distributed to people who cannot buy it or whether nicotinic acid should be substituted. My own experience would lead me to believe that the use of pure yeast is still the most effective control measure.

DR. TOM DOUGLAS SPIES, Cincinnati: I am overwhelmed with the pertinent discussion of this paper. Nicotinic acid is a constituent of food, and antipellagic foods such as yeast, wheat germ and liver are rich in nicotinic acid; foods such as corn meal, corn syrup and fat meat, which predispose to pellagra, contain little if any nicotinic acid. Contrary to Dr. Ruffin's impression, the dose of nicotinic acid prescribed for the treatment of pellagra is necessarily inconstant, because of the variation in the manifestations and severity of the disease. If Dr. Ruffin cured all of his pellagrins with only 70 mg. of nicotinic acid, given orally, he must have been dealing with mild forms. When he does preventive work with pellagrins he will note that the curative dose for one is not sufficient to prevent the development of the disease in another. To prescribe too small a dose is to run a risk and to lengthen unnecessarily the convalescence; to withhold nicotinic acid from severely ill pellagrins is to deprive them of the best single therapeutic drug now known. In regard to Dr. Mackie's point that the requirement for nicotinic acid seems greater in the alcoholic patient than in the patient with endemic pellagra, we found that the response to adequate amounts of nicotinic acid was uniformly dramatic in the series of cases, including

cases of both endemic and "alcoholic" types, studied at the Cincinnati General Hospital during September 1937. In reporting these observations before the Central Society for Clinical Research in Chicago, Nov. 5, 1937, we stated that nicotinic acid was an antipellagic factor and was life saving for moribund patients. Subsequent publications have confirmed our observations. We recommend that all patients with pellagra be given a well balanced diet, but if such a diet is not obtainable or if the patient is unable to ingest it, nicotinic acid should be used as a specific therapeutic agent. Although the minimal curative dose has not yet been determined, we have found 500 mg., in doses of 50 mg. each, given over a period of twenty-four hours, a safe, effective and cheap remedy. Concerning the effect of sunlight, no one at present is in a position to state anything with absolute certainty. Sunlight may precipitate certain lesions, but it does not account for all and is not of nearly so much importance as is improper nutrition. We are just as much interested in why in the majority of cases reported by Dr. Ruffin there was no effect from exposure to sunlight as we are in the cases in which there was such an effect, since in these cases, so far as Dr. Ruffin has described, there was the same environment, the same type of food was ingested and the pellagra was of similar severity.

HEARING AIDS FROM OTOLOGISTS' AUDIOGRAMS

AUSTIN A. HAYDEN, M.D.

CHICAGO

The first hearing aid man used, and he alone of all animals uses any artificial means to increase hearing, was the palm of his own hand. By cupping his auricle he focused and thereby intensified sound waves on the ear drum. To this day the hand is the most universal hearing aid.

Mechanical aids—tubes and trumpets of almost every kind, shape, curve, composition and construction, as

Fig. 1.—Alexander Graham Bell's original hearing aid.

well as fans, canes, chairs and innumerable other devices of the most ingenious design and elaborate construction—are mute evidence of an insatiable longing for better hearing.

A primitive transmitter, battery and receiver made up the original electric hearing aid that Alexander

Read before the Section on Laryngology, Otology and Rhinology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.
As 95 per cent of the approximately 50,000 portable instruments sold in the United States in 1937 for approximately \$5,000,000 were of the carbon transmitter type, only such instruments are considered in this paper.

Graham Bell constructed for his own mother. Although it amplified but little, it did focus sound waves more directly on the drum, was self retaining and had all the popular appeal of the electric gadget. From this, less than two years later, he perfected the first electric telephone.

Fig. 2.—Present day portable transmitter type hearing aid parts.

Development of the electric hearing aid was at first slow indeed. Despite numerous splendid efforts for prevention and amelioration of hearing loss, including the extension of lip reading, the introduction of the fundamental tone audiometer by Edmund Prince Fowler and Harvey Fletcher and the foundation of the American Federation of Organizations for the Hard of Hearing¹ by Wendell C. Phillips, the deaf person remained the really "forgotten man," as far as hearing aids were concerned, until sixteen years ago. Half a century had passed since the first instrument had been fitted, and yet essentially one, and only one, type of electric hearing aid was available for general use. No important improvement had been made in Bell's original hook-up.

In 1922 Hugo Lieber introduced the midget air receiver with the shaped ear tip and two years later his "booster amplifying unit." In 1932 he brought out the first portable bone conduction hearing aid, and bone conduction was soon used in half the hearing aids manufactured.

Today the portable carbon transmitter type of hearing aid is a complex scientific instrument of considerable precision. In addition to the original telephone circular type, still occasionally used, four air receivers (high, low, medium and broad) and three bone receivers (high, low and medium) are now available. Three transmitters and four amplifiers with dry cell batteries of 1.5, 3 and 4.5 volts are in general use.

With the use of various combinations of the foregoing parts (eight receivers, three transmitters, four amplifiers, three batteries), 288 different hearing aids of this series can be assembled, each designed to correct a certain degree of hearing loss at a definite location in the hearing range. This is known as selective amplification. By use of the artificial ear, the fundamental tone audiometer² and the noise meter, the amplification of

sound by the hearing aid can be determined and charted as to both frequency and intensity.³ This is termed the instrument response, and from it base-fitting charts are made.

As most tones of ordinary conversation lie between the frequencies of 256 and 2,500 cycles per second and as hearing aids are built and human ears are intended primarily to hear the human voice, the attention of patient, otologist and manufacturer is rightly centered on this frequency range. If the instrument is to fit the patient and the patient is not compelled to fit the instrument, certain considerations are essential.

For many years otologists have satisfactorily measured hearing, generally by use of the voice (whisper and forced whisper, ordinary and loud conversation), tuning forks, tubes, bells, whistles, watches, acumeters, monochords and similar devices. The use of such devices has been and is now the practice of medicine. Authorized by law and qualified by special training and otologic experience, otologists are best qualified to make these clinical tests. Especially is this true when hearing aids are to be prescribed.

The old methods of testing hearing, however, do not supply the information needed for prescribing modern hearing aids. Today hearing must be measured in

Fig. 3.—The results of comparative tests by air conduction at octave of Western Electric 6-A, Otologist Service and Maico Audiometers shown in composite audiograms of twenty-six moderately hard of hearing patients. A indicates the right ear and B the left ear. The patients were from the Chicago League for the Hard of Hearing, 64 East Lake Street, Gertrude Byrne executive secretary; the Ear, Nose and Throat Clinic, St. Joseph Hospital, and the author's office. Many of the patients who were tested at octave letter frequencies showed islands of hearing loss greater than 5 decibels at these intervals, emphasizing the necessity for continuous sweep measurements and the importance of letter calibration. In the right ear at 128 Maico reached the threshold in twenty-five of the twenty-six cases. At 4,096 Western Electric 6-A reached the threshold in twenty-two, Maico in twenty-four and Otologist Service in twenty-five. At 8,192 Maico reached the threshold in twenty-two and Otologist Service and Western Electric 6-A each in twenty-four. For the left ear the results were quite similar, as the chart shows. While these composite audiograms of this small number of cases, show some variation, establishment of a standard threshold level for calibration will probably correct much of this discrepancy. The Council on Physical Therapy of the American Medical Association will soon supply this.

terms of frequency (pitch) at octave and preferably at octave letter steps (especially for the most important range, from 512 to 2,500 cycles per second, the conver-

1. Now the American Society for the Hard of Hearing, Betty Wright, executive secretary, 1537 Thirty-Fifth Street N.W., Washington, D. C.

2. Howard A. Carter, secretary, Council on Physical Therapy of the American Medical Association, suggested the use of the word "fundamental" instead of "pure tone" to designate the vacuum tube audiometer.

3. Present models of four major manufacturers, Acousticon Corona-tion, Western Electric Ortho-technic, Radiocar Zephyr and the Sonotone Audicle, have all been tested and accepted by the Council on Physical Therapy of the American Medical Association. Much commendation is due these manufacturers for the improvements of the past six years.

sation range) and in terms of intensity (decibel loss). For this the fundamental tone audiometer is essential.

The fundamental tone audiometer is a vacuum tube instrument that produces tones, pure within certain limits, at frequencies calibrated at full or at half octaves or better still at octave letters from 128 or lower to 8,192 or higher cycles per second and at intensities calibrated in decibels of hearing loss. Here the tone of the time-honored tuning fork loses its objectionable, but inherent, element of decay and can be increased, decreased or held constant at any frequency with any intensity for any length of time the observer desires. All information the forks gave in the classic Weber, Schwabach, Rinne and other tests is obtained with greater ease, accuracy and speed by the audiometer.

Of the five audiometers now generally available, I have tested four clinically. These are Western Electric 6-A, Sonotone-Knudsen,⁴ Maico and Otologist Service. The results are shown in figure 3.

Wave form was good above, but not as good below, 1,024 cycles per second in each instrument. Whether this factor is really as important as most physicists and many otologists assume is yet to be determined. Actual clinical experience with deafened ears in the otologist's office, where painstaking observation is possible and the cooperation of capable hearing aid consultants is available, will furnish the deciding evidence. The final answer is the patient, not the laboratory.

The heterodyne beat circuit (two tubes) of the Western Electric 6-A audiometer required bringing to

and sweep frequency really continuous, the latter being very important for diagnosis of otologic disease and prescription of hearing aids.

The Sonotone-Knudsen, Maico and Otologist Service audiometers use single tube oscillator circuits. These are known to be more stable in performance

Fig. 5.—Sonotone Audioscope, a "master hearing aid." Just as the trial frame enables the patient to see through the lens combinations indicated by the retinoscope, the master hearing aid permits hearing through the component hearing aid parts as determined by the audiometer. Three of the four major manufacturers use these instruments: Radio Ear the Selsaphone, Acousticon the Aurogag, and Sonotone the Audioscope. 1. Transmitter. 2. Transmitter adapter replacing the cord of the portable hearing aid. 3. Transmitter receptors, 1, 2 and 3, into which transmitter adapters fit. 4. Transmitter switch connecting receptors 1, 2 and 3. 5. Battery switch. 6. Volt meter. 7. MI—amount of current passing through transmitter. 8. Vc—amount of current passing through receiver. 9. Vc—circuit (taking place of control button on hearing aid transmitter). 10. Volume indicator for receiver circuit. 11. Amplifier base to hold carbon chambers in position for testing. 12. Amplifier carbon chamber, low, standard, medium, high and three specials. 13. Compartments for receivers and cords: A (white) cord, to which the four midjet and the original circular air receiver can be attached; —2 (red), —4 (amber), —6 (green) cords to which high, medium or low pitched bone conduction receivers (oscillators) are attached. 14. Compartment for transmitters, air receivers and accessories. 15. Receiver switch, which throws any of the receivers (A, .2, .4, or .6) into circuit. 16. Pilot lights (white, red, amber, green), which indicate which receiver is in circuit. 17. Switch (to the left simplified, to the right amplified) by which the amplifier can be cut either in or out of circuit. The latter (to the left) is essentially Alexander Graham Bell's original hearing aid circuit.

Fig. 4.—Otologist Service audiometer. Intensity calibration on the right, frequency on the left. 1. Intensity knob. 2. Intensity dial; single decibel step calibration from 0 to 60 decibels A scale and from 50 to 105 decibels for air conduction (B scale); overlapping from 50 to 60 is provided for convenience in testing at the upper end of the lower A scale and the lower end of the upper scale (B scale). 3. Intensity switch for A and B scales. For air conduction measurements both A and B scales are used, reading from 0 to 105 decibels. For bone conduction measurements, the switch is set at B but readings are made from the A scale from 0 to 60 decibels. It is to be noted that the difference (decibels) between the figures of these two scales is 45 in every instance. This is the difference between the bone and the air conduction thresholds, that much more energy being required to reach the threshold through bone conduction. 4. On and off signal light. 5. Frequency control knob, giving actual continuous sweep. 6. Frequency dial and indicator, with calibrations at octave and octave letter intervals from 128 to 8,192 cycles per second. Forty-three test points are thus available for location of tone islands and tinnitus, study of diplacusis or other acoustic problems with 18 in the most important conversation range. This is all important for fitting hearing aids. 7. Frequency switch for low (to left lower numbers on dial) and high (to right upper numbers on dial) frequency scale. 8. On and off power switch registering in signal light at 4. 9. Air conduction receiver with soft rubber ear cushion. 10. Bone conduction receiver.

zero beat (setting on calibration) frequently. Background noise was not sufficiently cut down. Dial calibration should be more legible. Wave form was good

and less noisy in operation. Their wave form, however, is apt to be poor below, but good above, 1,024 cycles per second. This is especially true if continuous sweep frequency is provided in the conversation range.

Sonotone-Knudsen has excellent wave form throughout. It is well constructed and easy to operate. Its sweep frequency, while actually continuous, is above the conversation range, beginning at 2,500 cycles per second.

Maico has good wave form throughout but its "sweep check" is not actual continuous sweep frequency. The uniform zero level is commendable. It affords a modern means of testing hearing.

The wave form of the Otologist Service audiometer is admittedly not pure below 1,024 cycles per second. The octave letter and single decibel step calibrations and the sweep frequency, which is actually continuous throughout, were found to be of great value in locating tone islands and prescribing hearing aids. The lack of purity of wave form below 1,024 cycles per second seemed of little clinical importance, especially in fitting hearing aids.

4. Previously tested and reported in Hayden, A. A.: Audiometers and Hearing Aids, J. A. M. A. 110:723-725 (March 5) 1938.

Excellent features were found to be common to all. Clinical observations were quite consistent. With any of the instruments, hearing can be measured more accurately and rapidly than with any previous methods or instruments. The audiogram is the best means of recording hearing loss for diagnosis of otologic disease, fitting of hearing aids and medicolegal purposes (including the detection of malingering). Standardization will increase its value. Otologists and the hard of hearing are deeply indebted to the designers and manufacturers of audiometers.

In the belief that otologists, if enabled to prescribe hearing aids from their own audiograms, could be of even greater service in ameliorating the devastation of hearing loss, and in the further belief that manu-

Fig. 6.—“A” shows the hearing of the patient with and “B” the hearing of the patient without the hearing aid. The difference between the lines “A” and “B,” approximately 40 decibels, shows improvement made by the hearing aid. This improvement in terms of distance would be from 2 feet without to 10 feet of hearing with the hearing aid. Audicle prescription: response chart No. B-12, audicle combination C-7-6-4.5 volts, right ear.

facturers could therewith construct even better instruments—more closely adapted to the individual patient’s needs—and could fit these more rapidly, thus reducing the fatigue error, I suggested a study of this entire subject to the executives of the Sonotone Corporation. This company was selected because its announced policy was to use only otologists’ audiograms for fitting hearing aids and because it agreed to include in the study manufacturers of other acceptable instruments and to submit all data to the Council on Physical Therapy of the American Medical Association.

Fig. 7.—Chart of hearing of patient with conductive (middle ear) deafness; bone conduction normal or nearly normal (loss not greater than 10 decibels); air conduction poor (loss greater than 50 decibels); bone conduction aid prescribed. Audicle prescription: response chart No. B-6, audicle combination 451 C-3-4-1.5 V, right ear. Hearing improved from 3 feet to 25 feet.

For this type of deafness “hearing windows” have recently been advocated instead of hearing aids, especially when the ear is dry. In no instance was the hearing improved as much by the operation as it usually is by a hearing aid. The indications, if any, for the operation seem thus far to be largely cosmetic.

Accordingly, in the late summer of 1937 Otologist Service, Inc., was established independent of Sonotone Corporation. The Marvel audiometer was redesigned

and rebuilt as the Otologist Service audiometer. The responses of Sonotone audicles (hearing aids) were made into Marvel’s ingenious base-fitting charts on sheets of translucent paper that could easily be placed over audiograms for comparing (“matching”) the latter’s curves of hearing loss with the former’s curves

Fig. 8.—Chart of hearing of patient with perceptive (nerve) deafness; loss in air and bone conduction about equal; air conduction aid prescribed. Audicle prescription: response chart No. A-11, audicle combination 451 E-5-H-3 V, left ear. Hearing improved from 3 feet to 11 feet.

of sound amplification. Audiometers and these base-fitting charts were made available to a small group of otologists for this study.

Since Jan. 1, 1938, 1,000 audiograms have been made. Three hundred of these have been studied and “matched” and the component hearing aid parts assembled in the Audioscope (fig. 5) according to the otologist’s prescription. These “trial frame” fittings have been checked by speech intelligibility tests (syllable, word or sentence), by subsequent audiograms of the patient wearing the assembled hearing aid (fig. 6) or by both.

The results were surprisingly accurate. Ninety-two of the first hundred patients, all examined by one expe-

Fig. 9.—Chart of hearing of patient with mixed conductive deafness; bone conduction fair (average loss less than 20 decibels); air conduction poor (average loss greater than 50 decibels); bone conduction aid indicated. Audicle prescription: response chart No. B-6, audicle combination 451 C-3-4-3 V, right ear. Hearing improved from 18 inches to 18 feet.

rienced observer, preferred, from the 288 possible combinations already referred to, the exact combination the otologist had prescribed. One hundred and forty-six, examined by less experienced observers, chose combinations very close to the prescription, and most of the remaining fifty-four did not vary greatly in their choice from the prescription. In every instance the audiogram was invaluable in reducing the time and consequently the fatigue of the fitting.

Complete examination of the ears, nose and throat by the otologist, as well as a general physical examination by the family physician, with such laboratory and other special work as may be indicated, is essential to secure the best results. Many mistakes in fitting can be avoided by securing the cooperation of parents, teachers, nurses, ministers and members of leagues for

Fig. 10.—Chart of hearing for patient with mixed perceptive deafness; bone conduction loss from 10 to 20 decibels less than air conduction loss; air conduction aid prescribed. Audicle prescription: response chart No. A-13, audicle combination 451 E-1-B-3 V. Hearing improved from 18 inches to 9 feet.

the hard of hearing. With such help many more instruments will be prescribed and worn.

From this and other experience available, the following general rules are postulated: A hearing aid is indicated (1) when air conduction loss is greater than 25 decibels in each ear or (2) when air conduction loss is not greater than 85 decibels in the better ear. The vacuum tube amplified hearing aid often helps in cases of greater hearing loss.

Choice of a bone or an air conduction hearing aid depends on the character and relative amount of hearing loss by each type of conduction. The audiogram deter-

Fig. 11.—Chart of hearing for patient with mixed deafness (borderline case); bone conduction loss one half of air conduction loss; choice of air or bone conduction aid depending on (1) speech intelligibility tests with master hearing aid and (2) audiogram of patient wearing hearing aid. Audicle prescription: response chart No. B-7 or A-5, R-bone 451 C-5-4-3 V, R-air 451 E-1-M-4-5 V, right ear. Hearing improved by air conduction from 18 inches to 11 feet and by bone conduction to 13 feet.

mines this and classifies hearing loss as indicated in figures 7, 8, 9, 10 and 11.

Which ear should be fitted, right or left, is also indicated by the audiogram:

1. If the difference in air conduction is greater than 20 decibels and the difference in bone conduction is less than 10 decibels, fit the ear with the greater loss for air conduction.

2. If the difference in air conduction is less than 20 decibels and the difference in bone conduction is greater than 10 decibels, fit the ear with the smaller loss for air conduction.

Improvement of hearing, such as is shown in the accompanying table, is usually obtained.

Selective amplification is of great importance and in need of much more clinical study as well as more laboratory observation. Already the rule that "peaks of amplification" of the instrument should not be "matched" to peaks of better hearing in the audiogram is well established. Such matching produces distortion.

It seems logical and probable, but has not yet been proved to physicists' satisfaction, that the amplification of the hearing aid should be peaked at the valleys of hearing loss as shown by the audiogram. Verification by wide clinical experience (several thousand fittings) would be convincing evidence, even though full laboratory confirmation was lacking.

Despite the efforts of Newhart and his committee; the constructive genius of Fowler and Fletcher, Jones

and Knudsen; the leadership of Shurly for the Section on Laryngology, Otolaryngology and Rhinology in the House of Delegates of the American Medical Association; the enthusiasm of Wherry's bulletins of the American Academy of Ophthalmology and Otolaryngology; the fine papers of Nash and others read at the 1938 meeting of the American Laryngological, Rhinological and Otological Society; the continuous interest in research of the American Otological Society, and the work of the Council on Physical Therapy, directed by Howard A. Carter and the Committee of Consultant Otologists,⁵ otologists must immediately take greater interest in audiometers and hearing aids or else the use of the former and the prescription of the latter will be taken over by others not so well qualified to serve the hard of hearing.

Research such as Otologist Service, Inc., has initiated (coordinating the efforts of otologists, physicists and manufacturers of acceptable hearing aids) offers the ideal practical plan by which otology may continue to serve in this increasingly important field of its own domain and greatly benefit America's millions of deafened.

25 East Washington Street.

5. This committee is composed of Drs. George M. Coates, Lee Wallace Dean, Edmund Prince Fowler, Austin A. Hayden (chairman), Isaac H. Jones, Douglas MacFarlan, Burt R. Shurly, Horace Newhart and William P. Wherry, and Mr. Howard A. Carter (secretary).

WHAT AUDIOMETRY CAN NOW MEAN
IN ROUTINE PRACTICE

ISAAC H. JONES, M.D.

AND

VERN O. KNUDSEN, PH.D.

LOS ANGELES

The otolaryngologist is aware of a criticism directed at him. He is known to be devoted to every phase of his work except one field—service to the hard of hearing. Why is this? It seems to us that the fault is both in the patient and in the physician. The lack of interest in this field is easily explained. In his work as a specialist the otolaryngologist finds his real interest, just as specialists do in other fields, in a contented and satisfied patient. The otolaryngologist often sees definite results and on occasion has the satisfaction of knowing that he has actually preserved a life. He is human, and there is nothing that pleases him so much as a grateful patient. When it comes to the problems of hearing, however, he has found it very difficult to bring about a result satisfactory to the patient. The otolaryngologist is bound to feel at some time "Oh, what's the use!" He cannot help realizing that the patient puts a low estimate on his diagnostic studies. For example, a recent letter took nine pages to explain the history and symptoms and requested that an examination be made particularly for the purpose of prescribing a hearing aid. It ended "Do you make any charge for such a study?" Usually the patient who is hard of hearing is not satisfied unless his hearing is restored.

To be sure, one should not speak of "fixed" lesions; to do so expresses an attitude of hopelessness. The day when tuberculosis had the general reputation of being a hopeless condition can be recalled. Cancer is no longer regarded as necessarily fatal; many patients are saved by early diagnosis and treatment. In the spirit which improved the prognosis in these diseases, the physician must forever struggle on in the attempt to "cure deafness." At the present time much work is being done in this and other countries that gives promise of a brighter prospect. However, although the otolaryngologist must never permit himself to have a pessimistic attitude, he must face facts. Some more or less reasonable and many bizarre methods have been tried in the treatment of the chronically deafened, only to be abandoned. The physician no longer expects the ridiculously impossible, but most patients still do.

However, the physician should not be content simply to lay the blame on the extravagant demands of the patient. He deserves criticism if he is not ready to advise and direct the patient to the fullest extent possible. He must be prepared to meet the need. He is now able with precision to measure and diagnose conditions of the middle and internal ear and then to give intelligent advice or treatment. He can also, as the ophthalmologist has done for so many years, prescribe the type of aid best suited to each patient, and in many instances he can secure an instrument that will meet his prescription. The instruments of precision for diagnosis are available, and yet very few otolaryngologists use them. It is freely admitted everywhere that a careful study of a hard of hearing patient

should include the vestibular tests and audiometric tests with a standardized audiometer in a soundproof booth. Without the vestibular tests, only one half of the ear is examined; that is, the ear is only half examined. Yet the fact remains that in 1938 many otolaryngologists do not even possess a turning chair; some at last are securing audiometers, but soundproof booths, without which any hearing test is woefully inadequate, are practically unknown.

Besides the vestibular tests and the use of an audiometer in the soundproof booth, there is another test which we have found of such value that we have used it as a routine for fifteen years—a study of the mechanism of the middle ear by a pneumatic oscillator with an electric otoscope. To "see the ear hear" is not merely an attractive thought. To a great extent it is perfectly possible to accomplish this in clinical practice. Naturally, we cannot observe the motion of the drum membrane when it is exposed to sound waves. The motion is too tiny and too rapid. The ear is wonderfully sensitive. At a frequency of 1,000 cycles a barely audible sound is heard when there is a pressure variation of only one billionth part of atmospheric pressure in the auditory canal. At this threshold of hearing the drum membrane moves one billionth of an inch. For lower frequencies the excursion is somewhat larger. For an ordinary sound, such as the voice or the average noise in the office, the drum membrane moves one millionth of an inch. Such movements we are not able to see.

Again, we cannot see the drum membrane move because it moves too rapidly. The eye has detectors for only one octave, from red to violet; double the frequencies for red are sensed as violet. In the ear there are ten octaves, from twenty to twenty thousand cycles. We cannot see such rapid movements. "How, then, can we see the ear hear?" We can at least observe the motion of the drum membrane and hammer, and to this extent we can know exactly how well this portion of the ear can hear. An oscillator with the electric otoscope causes an alternate rarefaction and condensation. We can cause the drum membrane to move about one hundredth of an inch, and such excursions are plainly visible. As to frequency, we can cause the membrane to move three, four, five or any number of times per second. In this sense we are then able to "see the ear hear." Clinically we determine stapes fixation as follows: If the turning and caloric tests and the audiometric tests in the soundproof booth reveal a normal internal ear and eighth nerve, the deafness is proved to be due to a conductive defect and the oscillator with the electric otoscope shows normal texture and normal mobility of the drum membrane and hammer handle, we can conclude that there is only one diagnosis, one definite lesion, stapes fixation.

At long last the otolaryngologist is beginning to recognize that audiometry is not only a legitimate but a necessary part of his practice. He no longer inquires "Should I have an audiometer?" but rather asks "What kind of an audiometer should I get?" Not only are otolaryngologic societies attempting to standardize tuning forks and the tuning fork tests; they have committees at work setting up many minimal standards for acceptable audiometers, and they are earnestly endeavoring to establish educational programs for the teaching of audiometry (1) to active otolaryngologists and (2) to medical students, particularly those about to specialize in otolaryngology.

From the Department of Physics, University of California (Vern O. Knudsen).

Read before the Section on Laryngology, Otology and Rhinology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

Much progress has been made during the past year, and substantial agreement has been reached by the committees of the many societies as to the minimal standards for audiometers. Briefly, the standards set forth the following specifications:

1. The audiometer shall provide at least the following tones: 128, 256, 512, 1,024, 2,048, 4,096 and 8,192 cycles.

2. The intensity of the tones shall be controllable, and intensity steps corresponding to five decibel intervals (or less) shall be identified, both for air conduction and for bone conduction.

3. The frequency of any test tone shall remain within plus or minus 5 per cent of the designated frequency.

4. The tones produced by the air conduction receiver shall be free from audible overtones.

5. Extraneous noises must be inaudible.

6. The bone conduction receiver shall not produce sound in the air to the extent that the sound reaching the tympanum can influence the validity of the bone conduction measurements.

7. The air conduction receiver shall have an acoustic power output directly proportional to the electric power input.

8. The audiometer blanks shall use the same base line for both air conduction and bone conduction. In order that all charts may present the same visual impression, it is recommended that there be a ratio of 1 to 2 between the dimensions of a 10 decibel step and that of an octave step.

Good audiometers have developed to such a degree that the otolaryngologist is now able to purchase one with the assurance that it will not be necessary to make a trade for a new one for at least five or possibly ten years.

The audiometer should be set up in a very quiet room or soundproof booth. The accuracy of many hearing tests, especially by bone conduction, will depend

noise in the room. The faint tones would still be heard if it were not for this noise. Figure 1 shows the plan of a small inexpensive booth which can be built by any good carpenter; it will prove satisfactory if located in a reasonably quiet room.¹ In noisy locations a double-wall type of booth, such as that shown in

Fig. 2.—This booth is built on the principle of a "room inside of a room." That is, the inner room, with its own floor (of wood covered with fiber board), ceiling and door, is effectively separated from the outer room. The only points of contact between the two rooms are through the floor; the inner room should be supported by rubber pads as described in the legend for figure 1. The cost of this booth will be about \$150 to \$175. If ventilation is provided for this booth, care should be taken to prevent rigid connection between the outer and inner walls by means of the ventilating ducts; rubber or canvas connections will prove satisfactory. This booth will provide an insulation of about 50 decibels, but if it is to do this the doors must be locked tightly against rubber jambs and there must be effective isolation of the inner from the outer room.

Fig. 1.—A simple and inexpensive type of booth which can be constructed for about \$100. The ceiling should be constructed in the same way as the walls; for the floor the fiber board should be applied directly to the T and G subflooring. The door jamb should be lined with soft rubber so that the door will lock tightly against the jamb and thus eliminate all threshold cracks. If there is much vibration in the room where the booth is to be located it will be helpful to support the booth on 1 inch thick live rubber pads, one at each corner of the floor, of such size that the rubber is loaded to 6 pounds for each square inch of bearing surface. (Thus, if the booth and its contents weigh 600 pounds, each pad should measure 5 inches by 5 inches by 1 inch.) This booth will provide an insulation of about 30 decibels.

directly on the extent to which the room is free from noise. If the patient can hear any noise whatever in the room, the test tones will be heard not until they become inaudible but until they are masked by the

figure 2, is recommended. If ventilation is desired it can be provided by small supply and exhaust ducts, with a small electric fan used with either duct. Both the exhaust duct and the supply duct should be at least 6 feet long, should have a cross section of not more than 1 inch by 4 inches, and should be constructed of sound-absorptive material or of galvanized iron lined with one-half inch mineral wool blanket, such as one-half inch Fir-Tex, Masonite or similar material. Such ducts offer a high attenuation to sound and therefore will prove effective in eliminating outside noise. Although ventilation is desirable for a prolonged test, it is by no means necessary for routine work.

The following case reports are included for two reasons: (1) to present our methods in the study of patients and (2) to put on record certain unusual cases, the understanding of which would have been difficult without precision measurements. In fact, without precision measurements, the diagnosis in these cases would have resolved itself largely into a matter of mere guesswork.

The cases include one of chronic catarrhal otitis media in which the progressive deafness was stopped by surgical intervention fifteen years ago; three of otosclerosis (one patient was deaf at birth, in one case deafness manifested itself after adolescence and in the third case deafness appeared at the age of 47) and one case each of arthritis of the ossicular joints, sudden deafness

1. Knudsen, V. O., and Jones, I. H.: Bone Conduction, Arch. Otolaryng. 13: 489-505 (April) 1931.

from acute syphilis, neuroma of the eighth nerve, cerebral auditory defect and deafness from psychoneurosis.

CASE 1.—Chronic catarrhal otitis media. Mrs. G. L. M. had normal vestibular function and normal bone conduction. The defect was purely conductive. Each ear showed impaired mobility of the drum membrane and the hammer handle, a dull tympanic membrane and retraction, with shortening of the light spot. The patient had been becoming progressively deaf for several years. For two years she had had tinnitus, like a roaring or, at time, the ringing of bells. The tinnitus had gradually increased until it was very distressing. After tonsillectomy and resection of the septum the progressive deafness stopped entirely and the noises disappeared at once. There has been no recurrence in fifteen years.

We have been unable to find a record of a case like the following, in which not only was the child apparently born with otosclerosis but the focus had already involved the oval window and produced complete bilateral stapes fixation. No doubt there are many such cases and the only reason for their not being on record is that precision measurements are so seldom made. It is known that the focus of otosclerosis does not "appear" or suddenly develop after adolescence. Histologic studies have demonstrated this in a child aged 3½ years (Manasse), in a child aged 5 years (Siebenmann and O. Mayer, one case each), in a child aged 1 year and 10 days (Guild) and in a fetus aged 7 months (Guggenheim). After Guggenheim's observation in 1931, Bast demonstrated a similar condition in several fetuses. These authorities did not state dogmatically that the sections demonstrated otosclerosis; however, they described dystrophic bone showing the characteristics of otosclerosis.

CASE 2.—Otosclerosis. D. D., a boy aged 5, when first examined appeared to be a typical deaf-mute. He was able to make sounds but they were unintelligible. The mother had been in perfect health throughout pregnancy; the birth was normal in every respect; forceps were not used; the baby developed normally and had no disease in these first five years.

Dr. Gilbert Roy Owen demonstrated the presence of the bony internal ears by roentgenograms. We then considered that there probably was a lesion of both internal ears, produced before birth by an unknown cause; but audiometric measurements reversed this concept. The child was most intelligent, and by careful checking we were able to satisfy ourselves that our chart was accurate. In the right ear the average hearing by air conduction was 42 per cent but by bone conduction was 80 per cent. The left ear showed an average air conduction of 30 per cent but bone conduction was 80 per cent. The child heard well with the high quality amplifier both by our large laboratory model and by our portable model. His parents volunteered the information that he seemed to hear better in the presence of a noise. It therefore appeared evident that, although he did not have perfect internal ears, what kept him from hearing was definitely a conductive defect, bilateral. The oscillator with the electric otoscope showed normal texture and mobility of the drum membrane and normal mobility of the hammer handle in each ear. So perfect was the mobility that the impression was that he had never had any trouble of any kind in the middle ears, and the parents confirmed this. It seemed certain that no chronic adhesive process within the middle ears could be responsible for such a total conductive defect. In brief, he had a conductive impairment not due to a lesion of the middle ear. The function of each cochlea not only was good but was far better than the air conduction. There was only one location and one explanation to account for this conductive defect—stapes fixation in the oval window.

With a specially constructed instrument, a high quality amplifier, this boy can hear well. There is every hope that he will be able to speak perfectly after education of his cerebral

auditory centers. We then examined his sister, aged 7 years, and she showed a similar picture, although not of such marked degree.

CASE 3.—Otosclerosis. Miss E. G. L., who had typical otosclerosis, exhibited impairment of hearing shortly after adolescence (fig. 3).

CASE 4.—Otosclerosis. Miss J. L. showed perfectly normal vestibular function by means of the turning and caloric tests (fig. 4). The bone conduction showed good cochlear function (fig. 5). The hearing defect was purely conductive. The oscillator with the electric otoscope showed normal mobility and texture of the drum membrane and normal mobility of the hammer handle, indicating that the lesion was stapes fixation. Examination gave the same results for the two ears. At first the differential diagnosis was between arthritis of the ossicular joints and otosclerosis. The patient had had arthritis of the spine for years, with occasional exacerbations. However, the normal mobility of the visible parts of the conducting mechanism and the typical picture of otosclerosis demonstrated in her sister seemed to remove any doubt and to make the diagnosis one of otosclerosis.

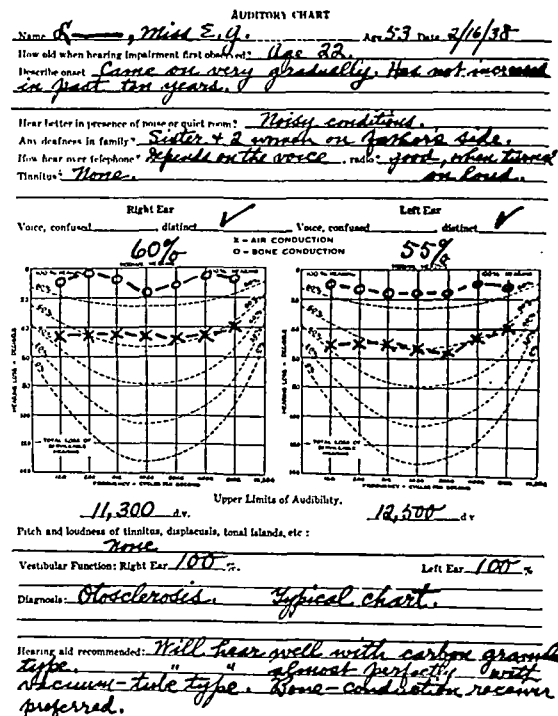

Fig. 3.—Audiometry chart, case 3.

Whereas patient 2 appeared to have been born with complete stapes fixation from otosclerosis, patient 4 had excellent hearing until she was 47 years of age. These two cases show that otosclerosis can involve the conducting mechanism at a widely variable time of life.

CASE 5.—Stapes fixation from arthritis. Mrs. H. C. had had a severe illness, from which she nearly died, which began with a throat infection, took the form of staphylococcal bacteremia and resulted in severe osteomyelitis of the spine. In the midst of this illness she became deaf in the right ear. Two years later the air conduction curve for this ear showed almost no hearing for the lowest tones, better hearing for the high tones and an almost normal upper limit of hearing, the classic curve of conductive deafness. Bone conduction was normal. The Weber test markedly referred to the right, the deaf ear. The oscillator with the otoscope demonstrated normal texture and mobility of both drum membranes and normal mobility of each hammer handle. In other words, there appeared to be nothing in the middle ear itself to account for this purely

conductive impairment in the right ear. A diagnosis was made of stapes fixation in the right ear, due to arthritis.

The patient was naturally fearful that she had otosclerosis and that she would soon become deaf in her other ear. She was assured that she did not have otosclerosis; that the lesion had happened once and for all, caused by the bacteremia, and

with saligenin and ten injections of neoarsphenamine. The patient promptly recovered his vision and the hearing was restored, according to the statement of the patient, to a degree "as good as it was before this happened." During this experience it was possible to observe the successive stages of improvement by audiometric measurements, just as Dr. Donohue could watch the fundi improve.

CASE 7.—*Neuroma of the eighth nerve.* R. S. had deafness which was easily diagnosed by the following sequence of events: The vestibular and auditory tests gave the usual picture of a neuroma of the left eighth nerve. Spontaneous nystagmus suggested that the neuroma disturbed the brain stem. When looking to the right the right eye went down; on looking to the left it went up and jerked to the left and down, and on looking up it went outward. At the first examination we asked the patient if he had any tumors in other parts of his body, and he showed a scar on his thumb, saying that a tumor had recently been removed. He was sent at once to Dr. Ray Taylor with a tentative diagnosis of multiple neurofibromatosis of von Recklinghausen (fig. 6). The remarkable report read: "There is indentation in the superior border of the petrous process on the left side. Immediately posterior there is an area of calcification, 1 cm. in diameter, lying close to the petrous portion of the temporal bone. This calcified mass appears to lie posterior and probably close to the internal auditory meatus." Then came the histologic report of the tumor that had been removed from the thumb—neurofibroma.

CASE 8.—*Cerebral auditory defect.*—E. F., a man aged 22, was generally regarded as a deaf-mute, although it was realized by those who knew him that he was not entirely deaf. He was obviously a mute in the sense that he was unable to talk; he could utter only meaningless noises. To our surprise we found that he could hear well. Not only did all tones and noises register in his cerebral centers, but he had good hearing for all tones. To check this fact, three audiograms were made on

that there was no reason for her to anticipate any trouble whatever in her left ear. Of course we had some mental reservations in stating such an opinion, but nine years has passed and she still has perfect hearing in her left ear. Clinically, this would seem to establish the diagnosis of arthritis of the stapes in its oval window.

CASE 6.—*Deafness and blindness from acute syphilis.* Mr. G. A. G. on arising in the morning noticed that he was deaf in both ears and had loud tinnitus like the noise of a steam whistle. He had determined to commit suicide. Although he was a cabinet maker of some intelligence, he followed the advice one reads in advertisements and went to a hearing aid concern for "diagnosis and treatment." Probably the only reason that he left the audiometrist and came to us, after many weeks was that he could not hear with any kind of a hearing aid that the audiometrist offered.

In this case it was obvious that the sudden deafness overnight was due to either hysteria or neuritis of the eighth nerves. The diagnosis was of course determined in a minute or two, simply by the turning chair. If he had shown normal vestibular responses we would have known at once that the condition was hysteria. The first glance at his throat showed a typical picture of acute syphilis. There were mucous patches on the oral mucosa and left tonsil, and the tonsillar region was swollen almost as in quinsy. Dr. William D. Donohue found that he was also going blind. The disks were swollen and the margins lost; the arteries were of normal size; the veins were congested and tortuous and appeared to bulge as they passed up and over the edge of the swollen disks; physiologic excavation was not yet wholly obliterated.

The Wassermann test with a 1:40 dilution of serum showed a reaction of 4 plus. Dr. Herbert A. Huntington gave vigorous treatment with a course of fifteen injections of iodobismutal

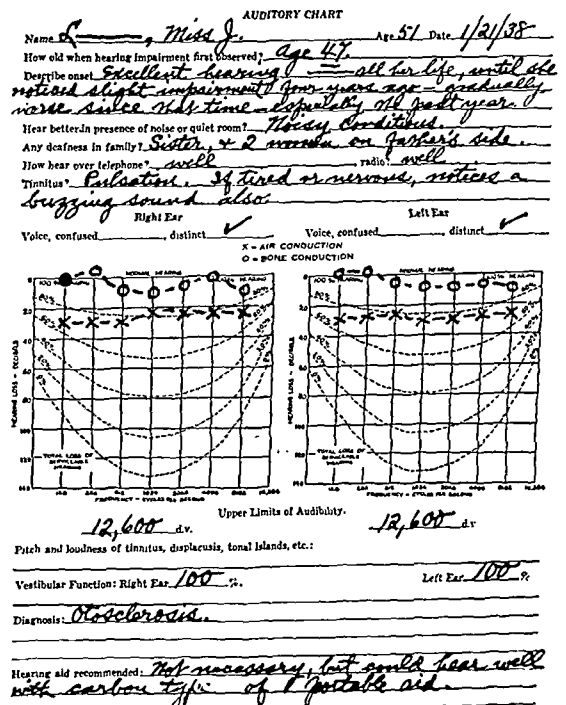

Fig. 5.—Auditory chart, case 4.

different days. He could reproduce tones; if some one hummed a certain note he could hum the same note. He could not speak, simply because he could not draw on the memory pictures of conversation that he had heard. He was unable to register and store up a concept of names and words. When he was 5 years old the family suddenly noticed that he did not understand what was being said to him and reached the con-

clusion that he was deaf. At the age of 2 he had had an illness diagnosed as encephalitis. At the age of 13 he suddenly jumped at the sound of an automobile horn, and the family then realized that he could hear. They naturally thought, however, that he could hear very little, because he did not understand speech and could not repeat words that were said to him.

The neurologic report of Dr. Eugene Ziskind gave the following facts:

1. Visual agnosia: There was no visual agnosia for objects or figures. The patient knew only a few words, possibly twelve; he was able to recognize the word "cat" in writing. His brother stated that it had never been possible to teach him the sign language for letters but that he was able to learn the code for words and communicated by this method. He could match colors shown him, but the only one he could recognize by name was blue. His brother stated that blue was one of the few words in his vocabulary. There was no loss of orientation, since the previous year the patient had hitch-hiked from Oklahoma to California. There was no acalculia; the patient was able to go to the store and did not permit himself to be short changed.

2. Auditory agnosia: He recognized the few words he knew. The examiner pointed to "cat" and said "Is this mamma?" He shook his head in the negative and said "titty" for "kitty." The examiner then pointed to the word "mother," which was one of the words he had written, and asked "Is this show?" He shook his head in the negative. When asked "Is this mamma?" he nodded in the affirmative. When asked to repeat, mamma, show and kitty, he did so. When asked to repeat words that he did not know, such as house, he failed to do so or made a sound which was irrelevant.

3. Aphasia tests: There was no spontaneous speech. He could repeat only words he knew. He did not understand the spoken voice, his understanding apparently being limited to the words he knew. He did, however, communicate by the sign language.

There was no apraxia and no agraphia. The patient wrote his name spontaneously, copied, transposed from print to writing and wrote from dictation the words he knew.

The diagnostic impression was that the patient probably had lethargic encephalitis in the epidemic of 1917-1918, at the age of 2 years, at which time a focal lesion produced partial motor aphasia and incomplete auditory aphasia. The patient showed partial visual agnosia for words, but since the pathologic lesion occurred before he learned to read or write it may be that the deficiency in this direction is to be ascribed to lack of training rather than to an organic loss. If one is to assume that the patient had visual agnosia in addition to the deficiencies noted, no focal localization is possible, and it may well be that the observations are to be explained by a diffuse lesion such as occurs in lethargic encephalitis.

CASE 9.—*Deafness from psychoneurosis.* Mrs. L. F. S., a gentle lady, had always prided herself on her acute hearing in both ears. Then came the railway accident. A wheel broke and the car went off the track; it did not turn over but pounded along over the ties. All the passengers were naturally excited, and some were in terror. The patient received no blow on the head. Three weeks later she noticed that she was deaf in her right ear and began to have pains on the right side of the head, especially above the right eye when stooping forward. Later she became hard of hearing in the left ear also. Several audiograms were made, and the curve was different each time. For example, in the right, deafer, ear she had an average the first day of only 25 per cent of hearing, the next day of 40 per cent and a few days later of 60 per cent. The vestibular tests showed actually hyperactive responses to turning and prompt responses to douching. It was clear that this elderly patient, as a result of a terrifying experience, had suffered a complete change in her outlook on life, and the diagnosis was clearly psychoneurosis.

It is a comfort to us to know that we need no longer have any concern about making a diagnosis of a functional hearing defect. The patient cannot deceive the audiometer. All that is necessary is to make two

or more tests. Of course the differential diagnosis between psychoneurosis and malingering is determined by other factors, especially the judgment of the examiner.

THE PRESCRIBING AND FITTING OF HEARING AIDS

The prescribing and fitting of hearing aids will never become as intricate as the art of prescribing and fitting eyeglasses; that is, the kinds and gradations of sound amplification needed are fewer than the many kinds and gradations of light refraction. The audiometer provides a necessary and dependable guide in determining the type of amplification best suited to each individual. The prescribing of hearing aids is a service the otolaryngologist should now be prepared to render.

Fig. 6.—Neuroma, case 7.

Obviously, the responsibility for audiometry and the prescribing of hearing aids can and should be assumed by the medical profession. Persons who practice audiometry should have a thorough knowledge of the relation of impairments of hearing to the diseases of the ear, nose and throat and to the entire human body, but they must know more than this. They must learn the basic facts of physical and physiologic acoustics and learn how to apply these facts to the technic of audiometry and the prescribing of hearing aids. This is not a difficult task. Although training in audiometry ultimately should be given by the medical schools, much can be done in the meanwhile by those otolaryngologists and collaborating physicists who are familiar with the technic and who recognize the importance of rendering audiometric service to the public. The acceptance of this responsibility by the physician will help to keep audiometry and the prescribing of hearing aids where it belongs—in the medical profession. If otolaryngologists do not assume this responsibility and assume it without delay, there will soon be a new type of practitioner, "the audiometrist," who will operate outside the control of medical standards.

The prescribing of hearing aids should be based on the following tests:

1. Careful audiometric tests both by air conduction and by bone conduction for the purpose of determining (a) the type of impairment and (b) the extent of the impairment throughout the useful range of hearing. In cases of nerve impairment it is necessary to determine the hearing loss not only for tones of threshold intensity but for tones having intensities comparable to those which comprise normal speech and music.

2. Speech articulation tests with different types of selective amplification. The audiometric tests ordinarily will indicate the approximate type of amplification with which the patient will hear best; but this should be confirmed, or modified as required, by actual speech tests, which will reveal the type of amplification with which each patient will hear best.

The technic of prescribing and fitting aids is one which calls for close cooperation between the medical profession and the manufacturer, similar to that which now exists between ophthalmologists and optical concerns. The doctor has the responsibility, therefore, not only of making audiometric tests but also of referring his patients to reputable concerns which are competent to make the fitting and guarantee their instruments.

Respecting the criteria for prescribing hearing aids, the following already may be regarded as established:

1. The prime requisite for every hearing aid is high quality amplification; that is, amplification which is free from the "peaked" responses and nonlinear distortions which have been so characteristic of the carbon type of portable aid used in the past. In the carbon type of aid the distortions are so great and the variability of amplification so unreliable that it does not seem feasible for the otolaryngologist to attempt to prescribe a particular type of selective amplification with such aids. Only in the vacuum tube type of amplification is the quality good enough to justify the planned control of amplification at different frequencies in such a way as to meet best the needs of each prescription.

2. In general, air conduction hearing aids should be prescribed for persons who have primarily nerve or perceptive impairment, and bone conduction aids should be prescribed for those who have predominantly conductive impairment. As yet it is not possible to set down any fixed rule for the prescribing of bone conduction aids or air conduction aids for that large group of patients who have mixed conductive and perceptive impairments. The work of our colleague Dr. Norman A. Watson has shown that persons with normal hearing can hear as well by bone conduction as by air conduction, provided the amplification is sufficient. However, the rule previously stated will be found to be a good one for the two extreme classes; that is, air conduction aids for persons in whom perceptive impairment predominates, and bone conduction aids for those in whom conductive impairment predominates. Often the convenience of wearing the aid will be an important factor. Women may prefer a bone conduction aid because they can conceal the receiver behind the ear. Men may prefer an air conduction aid because a molded ear piece obviates the need of a head band. There is nothing mysterious about bone conduction; it simply makes use of another route to the cochlea. If sufficient sound energy of the proper frequencies reaches the cochlea it matters little whether it gets there by air or by bone conduction.

3. For persons with purely conductive impairment or even predominantly conductive impairment, an amplification at each frequency equal to the hearing loss in decibels minus 20 decibels is found to be adequate. Owing to the presence of noise, which interferes with the hearing of every one, at least to an extent of 20 decibels, it is not necessary to provide as much amplification as the audiogram indicates; in other words, all persons speak much louder than would be necessary if they were in a quiet place. It will be found that the amount of amplification here indicated, namely 20 decibels less than the hearing loss, will be adequate for good hearing and also will provide a more comfortable level of loudness than would a greater amplification. Further, for such persons, experience shows that uniform, high quality amplification usually will be as satisfactory as any kind of selective amplification. The only exception to this rule would be for those who show a marked variation in hearing acuity throughout the hearing range.

4. For persons with purely perceptive impairment or with mixed conductive and perceptive impairment it is generally desirable to provide more amplification for the frequencies for which the hearing losses are large than for those for which the hearing losses are small. However, it is a serious mistake to prescribe an amplification equal to the hearing loss at each frequency. The work of many investigators has shown that for persons with perceptive impairment the hearing loss for tones of normal intensity is considerably less than the hearing loss for tones of threshold intensity. This is especially true for tones of high frequency, which are the ones most involved in cochlear or nerve lesions.

A patient who has been thoroughly studied by N. A. Watson, L. Sepmeyer and ourselves has an air conduction loss of 50 decibels at 128 cycles, gradually increasing to a loss of 90 decibels at 4,096 cycles, with complete loss of usable hearing for frequencies above 6,000 cycles. With no hearing aid and with a man calling words to him in a normal conversational voice from a distance of 2 feet, he was able to hear correctly 78 per cent of the vowels and 23 per cent of the consonants, which corresponds to a standard syllable articulation of only 4 per cent. With a woman calling the words he could hear correctly only 36 per cent of the vowels and 15 per cent of the consonants, which gives the negligible syllable articulation of only 0.4 per cent. With his portable aid (carbon microphone, carbon booster and electromagnetic receiver) he could hear correctly 76 per cent of the vowels and 54 per cent of the consonants, giving a standard syllable articulation of 21 per cent. With a portable vacuum tube aid he could hear correctly 100 per cent of the vowels and 70 per cent of the consonants, giving a standard syllable articulation of 45 per cent. With high quality vacuum tube amplification (a laboratory instrument, not portable) with equal amplification for all frequencies and with the optimal amount (42 decibels above threshold) of amplification, he could hear 100 per cent of the vowels and 80 per cent of the consonants, giving a standard syllable articulation of 60 per cent. When this uniform amplification was modified in such a way that the higher frequencies were given an amplification of 30 decibels more than the amplification provided for the low frequencies, he heard correctly 100 per cent of the vowels and 87 per cent of the consonants, giving a syllable articulation of 72 per cent. These results show

in a convincing manner (1) the advantage of high quality amplification and (2) the added advantage of the appropriate type of selective amplification.

These results are for one person, but they are based on an extensive series of tests, in which a total of 30,450 test syllables were employed. They are therefore reliable and accurate so far as this one person is concerned. Less exhaustive but similar tests on several other persons confirmed the conclusions drawn as to high quality and selective amplification.

It is our belief that these and similar observations open a new era for the hard of hearing, and recent trends in the development of vacuum tube aids in Great Britain as well as in this country indicate that a number of hearing aid concerns are aware of this approaching era.

It is true that the carbon or telephone type of aid has been developed to such a high degree that it has provided useful hearing for millions of hard of hearing persons who otherwise would understand speech only by lip reading or some form of sign language. Although such aids are often acceptable for intimate conversation, they fall far short of the necessary requirements for the satisfactory reception of speech in large rooms or for the distortionless amplification of music under almost any condition. The shortcomings of the carbon aid are particularly acute for those with advanced cochlear or nerve impairments. Often this type of instrument will overemphasize the background noise and reverberation to the extent that the nerve-deafened person will prefer not to hear rather than to suffer the loud and raucous noise produced by the instrument.

Even the most highly improved carbon type of hearing aid is subject to unavoidable distortions, inherent in the process by which it amplifies. The carbon type of instrument is capable of amplifying only a limited range of frequencies, about 300 to 3,000 cycles, and even for this restricted range there are undesirable "nonlinear" distortions. The first limitation means that those frequency components of speech and music which lie outside the restricted range, that is, below 300 cycles and above 3,000 cycles, are completely missing from the sound which has been amplified; the amplification is not uniform even throughout the limited range of frequencies for which the instrument does amplify, owing to the resonant action of diaphragms in the instrument. Nonlinear distortion means that the amount of sound which the instrument delivers to the ear is not proportional to the amount which strikes the microphone, and any instrument which responds in this manner introduces spurious frequencies in the amplified sound which did not exist in the original sound.

Vacuum tube amplification, the type used in the modern radio, is free from both frequency and nonlinear distortion; that is, it is capable of amplifying uniformly the entire range of frequencies which comprise speech and music, and it introduces no spurious frequencies. When a high quality microphone and a high quality earphone are used with a vacuum tube amplifier, the sound which reaches the ear is an amplified "facsimile" of the original sound. There are other meritorious features of vacuum tube hearing aids which every hard of hearing person should know: 1. Any required degree of amplification can be attained—sufficient for good hearing by bone conduction as well as air conduction—simply by using more vacuum

tubes, and this is accomplished without sacrificing the quality of the amplified sound. 2. The amplification remains constant day in and day out over a long range of the life of the batteries and is uniformly good for all positions of the hearing aid. 3. The adventitious or background noise is very low, and consequently the aid is free from the hissing sound so characteristic of the carbon type aids. 4. Since the amplification is uniform for all frequencies (that is, there are no "peak" responses for certain resonant frequencies), it is not necessary to adjust the loudness of the instrument to as high a level as is required for the carbon aid, in which it is necessary to adjust the loudness to a very high level in order that certain frequencies, which are not amplified so much as the resonant frequencies, will be heard with adequate loudness. 5. By means of appropriate electrical filters in vacuum tube aids it is possible to amplify selectively the low, medium or high frequencies and thus provide the type of amplification best suited for each individual.

Much has been said and written respecting selective amplification and the prescribing of hearing aids; perhaps too much has been claimed by certain proponents of these new developments. For many persons uniform amplification without distortion will be as good as, or better than, any other kind of amplification, but for other persons, especially those who have nearly normal hearing for low frequencies and a marked impairment for high frequencies, we have found that selective amplification is of distinct advantage. Criteria are already developed, based on audiometric tests, whereby it is possible to prescribe the best type of hearing aid for each patient with impaired hearing.

For those who want the best in hearing and are willing to make a slight sacrifice in portability, the vacuum tube type of hearing aid should be recommended. Also those who can afford to buy two instruments will find that the vacuum tube instrument will perform unusually well in many situations, such as in the office, at the bridge table or at musicals, where the more portable carbon aid will not be so satisfactory. Finally, many hard of hearing persons, especially those with a marked nerve or perceptive impairment, will find the vacuum tube aid so much better than the carbon aid that they should use it exclusively.

With the familiar carbon type of aid there was very little the physician could do for hard of hearing patients except advise those who needed an aid to try out several of the leading instruments on the market. Even if he knew how to write the prescription for the best kind and degree of amplification required for each patient, he realized that it would not be possible to fulfill these requirements by any possible combination of microphone, carbon amplifier and ear piece which make up the assembly of the carbon type hearing aid. With the advent of high quality aids of the vacuum tube type, however, audiometry and the prescribing of hearing aids takes on a new significance and the otolaryngologist is able to perform an indispensable service to his patients.

To recapitulate, these are the practical benefits of this service:

1. The otolaryngologist can measure the exact amount of hearing that each patient has both by air conduction and by bone conduction. This is a prime requisite for an intelligent approach to the hearing problem presented by every patient.

2. He can diagnose impaired hearing and determine how much of the impairment is of a conductive or purely mechanical type and how much of a cochlear, or perceptive, type.

3. He can determine whether any hearing aid should be recommended. Although there will be some exceptions, the following will serve as a working rule: All patients who have a loss in excess of 25 decibels (35 decibels at 4,096 cycles) throughout the range of 256 to 4,096 cycles should have a hearing aid.

(a) If the loss does not greatly exceed these limits, and especially if the loss is largely conductive, it is probable that the carbon type of aid should be recommended, because of its greater convenience and lower cost.

(b) If the loss is much greater than these limits, that is, if it is greater than 50 decibels throughout the range of 256 to 4,096 cycles, and especially if it is largely of the cochlear, or perceptive, type, a high quality vacuum tube aid should be prescribed.

(c) If the impairment is primarily conductive, a bone conduction type of receiver is indicated; if it is primarily perceptive, an air conduction type. If conductive and perceptive impairments are approximately equal, choice should be based on thorough test of both types.

(d) If the loss of hearing is largely perceptive and is much greater at high frequencies than at low ones, a high quality vacuum tube type with appropriate emphasis of the high frequencies is indicated.

4. If a definite choice of instrument is not indicated by the audiometric tests, recourse should be made to careful speech articulation tests.

As the science and art of audiometry progress, more specific criteria and procedures than those here presented will become established; but even now the otolaryngologist can and should take over the use of audiometry in serving his hard of hearing patients. If he does not, others will.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. HAYDEN AND DRS. JONES
AND KNUDSEN

DR. WILLIAM P. WHERRY, Omaha: Otolaryngology has been content to disregard the criticism of courts of law as well as of contemporary medicine, who have asked that methods be created whereby deafness can be allocated into ratios and percentages; that a record and a system be devised whereby a visual interpretation can be made by others than the person making the tests. Furthermore, that hearing aids for the deafened be prescribed by measurement, much as glasses are now, rather than by a trial and error method. Otolaryngology, therefore, must awaken from its lethargic poise and seriously consider ways and means to satisfy the demands now before it. Tuning fork tests primarily differentiate conductive from nerve deafness, which conclusion is of little interest to industry or courts of law. Likewise voice tests, with or without a poise apparatus as an adjunct, may be classified in the same way. "The potential variables among examiners makes accuracy of parallel recording almost impossible. The present day audiometers may be inaccurate; nevertheless, these instruments are tangible proofs that efforts are being made to develop a precision control. Within the past year a continuous frequency audiometer has been developed which can be produced on a low cost basis and which seemingly is giving a satisfactory return on both air and bone conduction. An audiometer built for clinical medicine may not be usable for research purposes; however, from the point of view of universal acceptance audiometer production must be approached from a low cost level even if specific instruments are to be built separately for research activities. The theme

developed in the papers for which this discussion has been prepared is timely. The art of medicine is as essential to good medicine as is the science of medicine; neither can be divorced from the other in clinical practice. Applying this commitment to the management of deafness, it should follow that examination records should be plainly interpretative and the facts visibly available to any one rechecking them. Only through some such program can otology hold a place in sound contemporary medicine. It must be granted that audiograms are a move toward the final objective, which objective has not been realized through tuning forks and voice tests. The ultimate objective will be in the offing when (1) audiometers are built simply and accurately for clinical use and (2) production is large enough to create a low cost level. I cannot close without saying a word of praise for the Council on Physical Therapy of the American Medical Association, which, through a sincere effort, has forced the issue of deafness evaluation on those who practice otology.

DR. HORACE NEWHART, Minneapolis: Audiometry has made possible extensive research which recently has yielded important basic knowledge concerning some of the unproved but suspected causes of impaired hearing and has made possible greatly improved means for making adjustments and providing compensating hearing devices for handicapping loss of hearing. It has opened to the medical profession the possibility of vast attainment in a neglected field of preventive medicine. Already the public school health program in many communities has been expanded to include the routine testing of the hearing of school children by scientifically accurate methods. This means the use of the audiometer. Several states have passed laws effectively providing for this procedure. The benefit which will follow its general adoption is incalculable. This procedure, to insure its satisfactory application, should be under the general supervision of interested qualified physicians and not be left to laymen, nurses and technicians. The situation demands the leadership of public-minded medical practitioners, especially otologists. The chief obstacle to the general use of audiometers in school health work has been the matter of expense. It should be made known that recently the cost of equipment has been materially reduced and the methods of application simplified, insuring greater accuracy and economy of time. Recently there has been made available at a low price a new, pure tone audiometer especially designed for use in schools. It is well constructed, is accurate in its performance and makes possible the testing of from thirty to sixty pupils per hour at fixed intervals of one octave from 128 to 8,192 double vibrations per second. It provides the means for detecting and measuring hearing acuity only by air conduction, thereby precluding its use for diagnosis or prescribing hearing devices. The temptation of the school nurse or technician to make a diagnosis is thus avoided. This type of audiometer will find extensive use in public schools, in college and university health services and in industrial medicine. In connection with the presentation of these instructive papers, attention should be directed to improvements recently made in hearing aids of the vacuum tube type. These have been so reduced in bulk and weight that they are now wearable like devices of the carbon microphone type. Since they afford much greater amplification than the latter, are remarkably free from distortion and intolerable internal noises and have a greater frequency range, they are especially adapted to the needs of those severely deafened persons who cannot be fitted by the carbon microphone hearing devices.

DR. HAROLD A. FLETCHER, San Francisco: The authors have spoken on the standardization of the audiometer. I have come more and more to use the audiometer. It is expensive and it makes the average otologist stop and think before he purchases one. I hope that the Council on Physical Therapy of the American Medical Association will soon publish a list of accepted audiometers. More otologists will buy audiometers when they are assured that they are getting an accurate instrument of precision. Drs. Jones and Knudsen mentioned the fact that otologists still must use all means of diagnosis, examination of the patient, the history and the general investigation. The use of tuning forks is still helpful. I think otologists go too far with diagnosis many times from the audiometer itself. It gives a picture of the air conduction loss in a patient with a comparative value of what tones, upper, middle or lower, are lost,

and the relative picture between them. It gives a fair idea of the bone conduction loss and it gives a basis of comparison of bone conduction loss and air conduction loss that is tolerably accurate. But we often forget the underlying pathology in the use of the audiometer and jump at conclusions from the mere curve. We should be cautious in advising the patient without taking into consideration the whole picture. I don't agree with Drs. Jones and Knudsen that one "can see an ear hear" with the electric otoscopic oscillator. The use of the oscillator is definitely helpful, but I know that when one exaggerates the movements to the drum so that they can be seen, one is not "seeing the ear hear"; one is seeing the drum membrane move under very abnormal conditions. Many times an important lesion of the ossicular chain aside from fixation of the stapes may be present and not show in the movement with the oscillator. I do not agree with Drs. Jones and Knudsen that one can make a diagnosis of otosclerosis in the case of a child at birth or at 5 years of age. Otosclerosis occurs in children younger than it was once thought, but I feel that it is impossible to make a diagnosis of otosclerosis with tests at that age. With the exception of those cases in which there is an indication to examine the vestibular apparatus, the vestibular examination has but little part in relation to the examination with the audiometer.

MR. HOWARD A. CARTER, Chicago: The Council on Physical Therapy of the American Medical Association, of which I am secretary, desires to recommend reliable and efficient apparatus for professional service. To aid the deafened, the Council is particularly interested in having on the accepted list efficient audiometers and hearing aids. A program for investigating the feasibility of fitting hearing aids by means of audiograms has been suggested in a paper by Dr. Austin Hayden. He proposes that audiograms taken by otologists in their own offices be referred to manufacturers or their representatives and from these data hearing aids will be made up according to prescription. After the hearing aid is delivered it is checked by suitable means to insure the best possible fitting. A thousand or more fittings, properly tabulated, will go far in establishing the advisability of selecting hearing aids by audiometric examination. An investigative program of this nature is indeed a step forward, and I hope that otologists will get behind the movement, thus enabling evidence of a critical nature to be accumulated as quickly as possible. As I understand it, this program is not confined to any one particular make of hearing aid but several manufacturers have been invited to participate. If the otologists do not take an active interest in fitting hearing aids, this important service will be taken over by other groups.

DR. DAVID HIGBEE, San Diego, Calif.: I realize this is a discussion about audiometry, but as Drs. Jones and Knudsen mentioned a few things that are off that subject I feel at liberty to make some statements about the diagnosis of fixed stapes. Drs. Jones and Knudsen stated that they require an oscillator to determine that the stapes is fixed or movable. Of course, that means that the membrana tympani must be intact or the oscillator would not alter its position. If a person shows a normal drum membrane and has normal bone conduction and a negative Rinne test, it certainly must indicate that the stapes is fixed. Bone conduction cannot be relied on as a certain guide to knowledge of the perception apparatus. Sometimes patients with perceptive deafness are seen who are Rinne negative. Guild has shown the pathologic condition which accounts for this phenomenon.

DR. ISAAC H. JONES, Los Angeles: Dr. Higbee and Dr. Fletcher feel that it is possible to "make a diagnosis without so much apparatus." At our recent state meeting, Dr. George Hosford showed us pictures of his office equipment in order to give his concept of a thorough study of the eye; we were all impressed with the enormous amount of apparatus. We know that many of our ophthalmologic friends spend many thousands of dollars for apparatus in order to do the best work possible; so is it not advisable for us to spend a few hundred dollars for a turning chair, an oscillator and an audiometer in a sound-proof booth in order that we also may do the best work possible? To be sure, the oscillator with the electric otoscope cannot enable one to "see the cochlea hear"; but it does enable the otologist to make a careful study

of the mobility of the drum membrane and the hammer handle. It does not give direct information regarding the joint of the malleus and incus, but an arthritis of that joint would probably not permit normal mobility of the hammer. For the past twenty years we have seen several cases in which we made a clinical diagnosis of arthritis of ossicular joints, although we have no histologic evidence. With a smile, we have always said that when so many thousands of people are killed by automobiles, isn't it strange that not one of these cases has come to autopsy? However, we have no doubt that arthritis of the ossicles does occur and we suggest that all might bear this in mind in studies of lesions of the conductive mechanism. In brief, we believe in precision measurements of the ear and consider that every possible means should be used to secure the fullest information about our patients.

EXPERIMENTAL POLIOMYELITIS BY THE TONSILLOPHARYNGEAL ROUTE

WITH SPECIAL REFERENCE TO THE INFLUENCE
OF TONSILLECTOMY ON THE DEVELOPMENT
OF BULBAR POLIOMYELITIS

ALBERT B. SABIN, M.D.

NEW YORK

The purpose of this communication is to present evidence (1) that the tonsillopharyngeal region is more highly sensitive to injections of poliomyelitis virus than are certain other regions of the body (e. g. the abdominal cutaneous or subcutaneous tissues) and (2) that the disease which results from infection by the tonsillopharyngeal route is, with few exceptions, bulbar or bulbospinal in type and different in its clinical course from that which follows nasal instillation of the virus. The present investigation was prompted by several clinical reports of cases of bulbar poliomyelitis following within a relatively short time operations of tonsillectomy and adenoidectomy. Ayer¹ (1928) appears to be the first to have noted the development of bulbar poliomyelitis in nine individuals within five to ten days after tonsillectomy. In 1929 Aycock and Luther² reported that, of thirty-six cases of poliomyelitis with a history of tonsillectomy within one year, the disease had developed in sixteen (eleven of which were of the bulbar form) from seven to eighteen days after operation, while there were no cases under seven days and none from the eighteenth to the thirtieth day. Silverman³ observed five cases, in four of which there was palatal paralysis and in one weakness of the neck muscles, which occurred from nine to nineteen days after operation. In the 1935 outbreak in New York City, Fischer and Stillerman⁴ found ten patients (among 686 cases) who had their tonsils and adenoids removed within a month of the onset of poliomyelitis. In eight of these ten the disease developed between the tenth and twelfth days after operation and in the other two on the sixteenth and twenty-second days; six of the ten patients had the bulbar or encephalitic form of the disease. During a small outbreak in 1937 Stillerman and

Fischer⁶ found three cases in which there was a history of tonsillectomy during the month preceding the illness among fifty-two poliomyelitis patients; all three had the bulbar form of the disease and the interval between operation and onset was fourteen days in two and twenty-one days in the third. While a large number of children are ordinarily submitted to tonsillectomy and adenoidectomy during the summer months and the occurrence of poliomyelitis among some of them may perhaps not be unexpected, it is the relatively high incidence of bulbar involvement among them that leads one to suspect that these operations may perhaps not only have favored the development of poliomyelitis but also influenced the special localization of the disease.

Experimentally there has been very little work done heretofore on the tonsils or pharynx as a route of poliomyelitis virus infection. In 1911 Landsteiner⁷, Levaditi and Danulesco⁸ reported that submucous injection into the tonsillar area of a monkey resulted in poliomyelitis. Levaditi and Danulesco⁷ showed that painting or rubbing the tonsils of three monkeys with virus failed to induce the disease, while application of the same virus to the nasal mucosa was followed by typical poliomyelitis. It is a common observation that, when virus is instilled intranasally in the amounts ordinarily used in rhesus monkeys, most of it runs down into the pharynx and mouth. The almost regular failure of the disease to develop following nasal instillation in monkeys whose olfactory pathways had been interrupted⁸ suggests therefore that contamination of the intact structures of the pharynx and mouth does not supply a suitable site for the entry of the virus.

It appeared desirable, therefore, to investigate (1) whether the presence of an open wound such as would follow a tonsillectomy operation might open a new portal of entry for the virus and (2) to determine the ease with which poliomyelitis could be induced by injecting the virus into the tonsillopharyngeal region and whether or not the disease so produced would be different from that which follows other modes of inoculation. It was clear from the beginning that, working with virus in the pharynx and mouth, it would be very easy to contaminate the nasal mucosa and that, unless some method of barring the olfactory pathway as a portal of entry for the virus was employed, the results might be confusing or difficult to interpret. Since the 1 per cent zinc sulfate nasal spray has proved effective in our hands,⁹ as in those of Schultz and Gebhardt,¹⁰ in preventing poliomyelitis in almost all monkeys receiving virus by nasal instillation, this method was chosen to close the olfactory pathway while studying the effect of tonsillectomy as a possible means of opening a new portal of entry for the virus. Histologic examination

of the olfactory bulbs¹¹ of monkeys succumbing to the disease provided another means for ascertaining whether or not the virus had reached the central nervous system by a pathway other than the olfactory.

Do Tonsillectomy Wounds Open a Portal of Entry for Virus Administered by Spraying, Swabbing or Nasal Instillation?—Two series of experiments were conducted in an attempt to obtain an answer to this question. In the first series four *Macacus rhesus* monkeys were given a nasal spray of 1 per cent zinc sulfate ($\text{ZnSO}_4 \cdot \text{H}_2\text{O}$), thirty bulb compressions from a De Vilbiss atomizer for each nostril, once a day for two days. Two days after the last spray the palatine tonsils were removed by dissection under ether anesthesia. (It may be stated here that the tissue removed had the same histologic structure as the human palatine tonsil, although for the purpose of these experiments the presence of the operative wound was the essential factor.) Within one hour of the operation 1 cc. of 5 per cent virus suspension was instilled into each nostril (virus entered throat and mouth) and the same dose was repeated four hours later. Employing pooled M. V. virus, glycerolated for not longer than one month, this procedure has led to the development of poliomyelitis in practically all control monkeys (over 100) in the past two years;¹² three control animals given the same virus suspension developed poliomyelitis. Two of the zinc sulfate-treated and tonsillectomized monkeys received additional amounts of virus—3 cc. sprayed onto the wounds at each nasal instillation. None of the four treated animals, however, developed poliomyelitis and daily temperatures for a month revealed no fever.

In the second series four monkeys received the same zinc sulfate nasal spray as in the preceding experiment. The operation was performed twenty-four hours after the last spraying and differed from the preceding one in that the operative field was flooded with virus in order that the instruments might grasp and cut through contaminated tissue. After the removal of each tonsil and the cessation of bleeding, thick virus-containing tissue (sediment from 5 per cent virus suspension) was swabbed into the wound. Before the monkey recovered from the anesthesia, 3 cc. of 5 per cent virus suspension was sprayed into the throat. On the afternoon of the same day, and twice a day during the following two days, each monkey was again sprayed with 4 cc. of virus. None of these four animals exhibited any signs of disease; in two control monkeys receiving the usual nasal instillation with this virus suspension poliomyelitis developed.

That the monkeys used in these two experiments were not resistant animals to begin with and had acquired no immunity as a result of the repeated virus sprays is evident from the fact that they succumbed with typical poliomyelitis following nasal instillation of the virus after the effect of the zinc sulfate had disappeared.¹³ It seemed, therefore, that in monkeys the wounds created in the oropharynx by tonsillectomy failed to establish a portal of entry for poliomyelitis virus (M. V. strain) applied by swabbing, spraying or nasal instillation when the olfactory pathways were blocked by zinc sulfate nasal sprays prior to operation.

Does the Deposition of Virus Within the Tissues of the Tonsillopharyngeal Region (as by Injection) Lead to the Development of Poliomyelitis?—The preceding experiments emphasized again that in the monkey the olfactory mucosa is the only known peripheral tissue which by mere transitory¹² contact of its surface with the virus of poliomyelitis can permit it to invade the central nervous system. When relatively large amounts of virus are deposited within certain tissues, as by subcutaneous or intracutaneous injection, the disease may be induced in a varying, though usually small, number of monkeys. The chief purpose of subsequent experiments was to determine (a) whether injection into the tonsillopharyngeal region of amounts of virus usually employed for nasal instillation would give rise to poliomyelitis with any degree of frequency, (b) whether the disease so induced would be different from that following nasal instillation of virus, and (c) how inoculation by the tonsillopharyngeal route compared with injections of identical amounts of the same virus by the subcutaneous and intracutaneous routes.

In the first experiment of this series six monkeys received zinc sulfate nasal sprays as described before. Three days after the last spray the virus was administered to three monkeys by nasal instillation (1 cc. of 5 per cent suspension in each nostril on two occasions) and to the other three by injection of 1 cc. of the 10 per cent suspension into each tonsillar region. The latter inoculation was usually performed by grasping the anterior pillar of the fauces to evert the palatine tonsil, into which the needle was inserted, infiltrating the tonsil and surrounding tissues as the needle was being thrust deeply as far as the bone. Three normal monkeys which received virus intranasally for control developed poliomyelitis. Of the zinc sulfate treated animals those receiving virus by nasal instillation remained well, while poliomyelitis developed in two of the three in which virus was inoculated into the tonsillopharyngeal region; one of these two had the distinct bulbar form including aphonia and paralysis of the face and of the muscles of mastication, while in the other the first sign was head drop, which was quickly followed by flaccid paralysis of the upper extremities. In the following experiment poliomyelitis developed in four of six zinc sulfate treated monkeys inoculated with 1 cc. of 10 per cent virus suspension into each tonsillar region, three of these being of the bulbar type; six zinc sulfate treated monkeys which were given the same amounts of the same virus suspension subcutaneously in the right and left lower abdominal quadrants remained well. In the next series the same amount of virus was injected intracutaneously (in ten piqures on the abdominal skin) and into the tonsillopharyngeal region of normal monkeys, i. e. without any preliminary chemical spraying of the nasal mucosa; the six monkeys injected intracutaneously remained entirely well, while poliomyelitis developed in all six of the tonsillopharyngeal group, five of them having the typical bulbar disease. In the same experiment there were five monkeys which, having had zinc sulfate nasal sprays from one to three months before and having resisted virus by nasal instillation or pharyngeal spray, were inoculated with 1 cc. of 10 per cent virus suspension in each tonsillar region; poliomyelitis developed in four of these five, all of the bulbar type. In one of the experiments it was found that, when 0.2 cc. (instead of 1 cc.) of the virus suspension was injected superficially into the tonsillar area of six monkeys, all remained well. In another group of six

monkeys which received 0.2 cc. into each tonsillar area, tonsillectomy was performed immediately after injection to determine whether the trauma and cutting through the virus-containing tissue would facilitate the development of poliomyelitis; all of these remained well. In a similar group of three, however, in which the tonsillectomy was followed by swabbing of the wounds with virus tissue and subsequent sprays of 10 per cent virus suspension into the throat, one animal acquired typical bulbar poliomyelitis (including aphonia, impaired deglutition and salivation) on the fourth and died on the fifth day. One cannot tell here whether any of the special procedures were responsible or whether in an occasional monkey even 0.2 cc. of virus may produce the disease, in spite of the fact that most of it was almost immediately removed during the tonsillectomy.

Altogether there were twenty monkeys which received injections of 1 cc. of 10 per cent virus suspension into

Clinical course of experimental poliomyelitis in monkeys.

each tonsillar region; poliomyelitis developed in sixteen of these (80 per cent) and among them there were thirteen cases of the bulbar type. None of the twelve monkeys which received injections of the same amounts of virus intracutaneously or subcutaneously (abdominal region) exhibited any signs of disease. It is, of course, known that an occasional monkey receiving subcutaneous injections of this strain of the virus (particularly with large amounts) acquires poliomyelitis, but the simultaneous tests in the present study show rather conclusively how very much more susceptible is the tonsillopharyngeal region. It has been stated¹⁴ that there are certain strains of the virus which, early after their isolation from human beings, are somewhat more infective by the intracutaneous route than is the M. V. strain which was used in these experiments, and it is quite possible that they might be more highly infective also by the tonsillopharyngeal route.

Clinical Course of Disease Following Nasal Instillation Compared with That Induced by Tonsillopharyngeal Injection of the Virus.—A most striking and practically constant manifestation of the disease induced

14. Trask, J. D., and Paul, J. R.: The Skin Infectivity of Poliomyelitis Virus, *Science* 87: 44 (Jan. 14) 1938.

by nasal instillation of the virus is that the first rise in temperature occurs at least three to five days before the first appearance of nervous signs. The temperature then either remains elevated or drops considerably (sometimes practically to normal) within a day or two and usually rises again before the onset of paralysis (dromedary curve). After injection of the virus into the tonsillopharyngeal region, however, the course of events is quite different: among seventeen such monkeys in which poliomyelitis developed there were four in which no rise in temperature was observed, six in which fever and paralysis appeared on the same day, and seven in which the rise of temperature preceded paralysis by

one day. Again following nasal instillation, paralysis practically never appears before the sixth day, and usually not before the seventh or eighth day, while after inoculation into the tonsillar region it appeared on the third day in one monkey, on the fourth day in six, on the fifth day in three, on the sixth day in four, and one each on the seventh, eighth and eleventh days. Furthermore there was a distinct difference in the structures which became paralyzed after the two routes of infection. In the past two to three years I have observed more than 250 monkeys in which poliomyelitis developed after nasal instillation of the virus, and table 1 presents an analysis of the incidence with which the various structures were affected first.

It will be noted that following nasal instillation the disease begins with cranial nerve palsy (chiefly third and seventh cranial nerves) in only about 6 per cent of the cases. The complete bulbar picture with aphonia, impaired deglutition, salivation or paralysis of the muscles of mastication was not observed even once, although two monkeys died apparently of respiratory failure or at least without the appearance of any observable paralysis and with histologic changes predominantly at levels above the spinal cord. After tonsillopharyngeal injection of the virus the picture was quite different (table 2).

To illustrate the sequence of events in monkeys receiving virus by injection into the tonsillar region, several protocols will be abstracted:

MONKEY 1.—The temperature was normal (from 101.8 to 102.7 F.) and the animal appeared entirely well for two days after injection. On the morning of the third day the temperature was 105.1; there were weakness of the facial muscles and the muscles of mastication, salivation, and a peculiar cry; the head was erect and the extremities were strong. In the afternoon of the same day the temperature was 105.2; there were complete aphonia with obstructed respiration, impaired deglutition, salivation, complete bilateral facial paralysis and complete paralysis of the muscles of mastication; the sensory fifth nerve, the eyes and the tongue were normal; there was head drop to the left. The upper and lower extremities were strong. On the fourth day at 9 a. m. the monkey was prostrate with a temperature of 98 and labored respiration; it died one hour later.

MONKEY 2.—The temperature was normal (from 102 to 103.5 F.) and the animal was well for the first two days. On the third day it was 107 in the forenoon and 106.2 in the afternoon

but there were no detectable nervous signs. On the fourth day the temperature was 104.7 and there were incomplete aphonia, paralysis of the muscles of mastication, partial head drop and complete paralysis of the right arm; involvement of the facial muscles and deglutition were questionable. On the fifth day the temperature was 99; there were complete aphonia and inability to swallow liquids or solids, and paralysis of the muscles of mastication. The facial muscles were weak, the tongue was normal and there were complete head drop and flaccid paralysis of the upper and lower extremities. The monkey was killed at this stage for study of its nervous system.

MONKEY 3.—The temperature was normal (from 101.7 to 103.3 F.) for the first five days. On the sixth day it was 106.3 and there were complete right facial paralysis and no other nervous signs. On the seventh day the temperature was 103.5 and there were right facial paralysis, aphonia, head drop, and paralysis of all extremities; the muscles of mastication were normal, and deglutition and tongue movement were questionable; this monkey was killed in the afternoon of the same day (the temperature then was 101.5 F.) for study of the nervous system.

MONKEY 4.—The temperature was normal (from 102.2 to 102.5 F.) for the first four days and the temperature was 105.5 but the monkey was otherwise well on the fifth day. On the sixth day the temperature was 107.3; there was paralysis of the right arm but no other nervous signs. On the seventh day the temperature was 104.8; both arms were paralyzed. On the eighth day the temperature was 103.4; there was paralysis of the arms and legs but no other involvement. The animal was killed.

MONKEY 5.—The temperature was normal (from 102.7 to 103.5 F.) and the animal was well for the first three days. On the morning of the fourth day the temperature was 103.2 and there were salivation, incomplete aphonia, paralysis of the muscles of mastication and complete right facial paralysis, deglutition was questionably impaired, the tongue was normal, there was head drop to the right with inability to raise the left arm above 180 degrees, and the lower extremities were uninvolved and strong. In the afternoon of the same day the temperature was 101.1, the aphonia and head drop had become complete, the facial paralysis was bilateral and there were distinct nystagmus and partial paralysis of both arms, the legs still being strong. The animal was found dead on the morning of the fifth day.

TABLE 2.—Order in Which Structures Were Affected After Tonsillopharyngeal Injection of Virus

Bulbar paralysis first (i. e., aphonia, impaired deglutition, paralysis of muscles of mastication, with or without facial, head drop or other paralyses).....	13	(76.5%)
Head drop or paralysis of upper extremities or both, first (these never showed bulbar signs).....	3	(17.6%)
Facial paralysis first.....	1	(5.9%)
Lower extremities first.....	0	
Total.....	17	monkeys

MONKEY 6.—The temperature was normal (from 101.7 to 103.7 F.) and the monkey was well for ten days after injection. On the eleventh day the temperature was 103.6 and there were incomplete aphonia with difficult respiration, salivation with inability to swallow solids or liquids, bilateral facial paralysis and paralysis of the muscles of mastication, the tongue was normal, and there was head drop with complete paralysis of the right arm and inability to raise the left one above 180 degrees. The legs were uninvolved and strong. The monkey was found dead on the morning of the twelfth day.

The difference in the clinical picture of the disease induced by nasal instillation and by tonsillopharyngeal injection of the virus is exactly what one would expect on the basis of the probable progression of the virus from each site. Faber and Gebhardt¹⁵ have already

¹⁵ Faber, H. K., and Gebhardt, L. P.: Localizations of the Virus of Poliomyelitis in the Central Nervous System During the Preparalytic Period, After Intranasal Instillation, *J. Exper. Med.* 57: 933 (June) 1933.

shown by subinoculation experiments that nasally instilled virus involves progressively the olfactory bulbs, hypothalamus, thalamus and other higher centers before it reaches the spinal cord and gives rise to paralytic signs. In as yet unpublished studies I have observed neuronal lesions progressively in the olfactory bulbs, the region of the anterior perforated space, hypothalamus, thalamus and midbrain (especially substantia nigra) of such monkeys, and it is more than probable that the three to five day period of fever preceding the onset of paralysis is a reflection of the progressive involvement of at least some of these higher centers. After tonsillopharyngeal injection, however, the clinical picture indicates that in most if not all of the monkeys the virus that enters along the nerves supplying the region comes into immediate contact with the cranial nerve nuclei, the involvement of which leads to the typical bulbar form of the disease. Histologic studies have not yet been completed, but it is already evident that extensive lesions are present in many of the cranial nerve nuclei in the medulla and that the olfactory bulbs which are constantly involved following nasal instillation¹¹ were, with one exception referred to later, free from lesions.

Test for Virus in the Olfactory Bulbs and Nasal Mucosa of Monkeys Infected by the Tonsillopharyngeal Route.—In a previous study¹² it was found that, when infection occurs after nasal instillation, virus could be demonstrated in the olfactory bulbs from the third day to the termination of the disease, even though the nasal mucosa was only slightly infective and for a very short time early in the disease. The statement is commonly found in the literature that the nasal mucosa of the monkey is not only a good portal of entry for the virus but also a place for its exit. It is obvious that if the latter is generally true one cannot use the finding of virus in the human nasal secretions or mucosa as a point in favor of that region being the natural portal of entry. It appears, however, that the few positive observations on which the assumption of its nasal exit is based were obtained in monkeys that received the virus intracranially and that the results, therefore, might not be the same when the virus had invaded the central nervous system by way of certain peripheral nerves. Furthermore, it was desirable to determine to what extent the presence or absence of virus (as well as lesions) in the olfactory bulbs could be used as an index of whether or not the olfactory pathway had been used for invasion of the central nervous system, i. e. whether or not virus having entered some medullary nucleus would spread as far as the olfactory bulbs by the time the monkey died or was prostrate.

In the first series of tests there were four monkeys, all of which had received zinc sulfate nasal sprays before tonsillopharyngeal injection of the virus. Three of these had the bulbar type of the disease and the fourth had only paralysis of the extremities; one had died within twenty-four hours of the onset of paralysis, and the other three were killed when nearly prostrate, one, two and three days respectively after the onset of paralysis. Both bulbs were removed from each monkey with special precautions. A piece of each was sectioned and the rest ground in salt solution, and the entire suspension injected intracranially into a monkey. Neither a lesion nor virus was found in the olfactory bulbs of any of these monkeys.

In the second series of tests there were four monkeys which received no preliminary treatment of any kind

before tonsillopharyngeal injection of the virus. All had bulbar poliomyelitis. Two died within twenty-four hours, and the other two were killed when nearly prostrate on the third day after the onset of paralysis. The olfactory bulbs were studied as before, and in addition

TABLE 3.—Summary of Experiments

Experiment	Preliminary Treatment	Mode of Experimental Infection	No. of Monkeys Used	Total No. Developed Poliomyelitis	Number with Bulbar Signs
a	1% zinc sulfate nasal spray for 2 days before bilateral tonsillectomy	Nasal instillation after tonsillectomy with subsequent sprays of 10% virus into throat	4	0	—
	None (virus controls)	Nasal instillation	3	3	0

		Injected by tonsillopharyngeal route; 1 cc. 10% virus on each side	6	4	3
		0.2 cc. 10% virus injected into each tonsillar area	6	0	—
		0.2 cc. 10% virus injected into each tonsillar area, followed immediately by tonsillectomy	6	0	—
		0.2 cc. 10% virus injected into each tonsillar area, followed immediately by tonsillectomy, swabbing of wounds with virus tissue, and subsequent sprays of 10% virus into throat for 3 days	3	1	1
e	None	Intracutaneous injection; 2 cc. 10% virus in 10 pinpricks in abdominal skin	6	0	—
		Injected by tonsillopharyngeal route; 1 cc. 10% virus on each side	6	6	5
	1% zinc sulfate nasal spray followed by virus instilled into the nose or sprayed into throat 1 to 3 mo. before present experiment; none of the monkeys had any signs of disease	Injected by tonsillopharyngeal route; 1 cc. 10% virus on each side	5	4	4

the entire nasal mucosa of each monkey was tested for virus. No virus was found in the nasal mucosa of any of these animals, and the olfactory bulbs of three of them contained neither virus nor lesions. The olfactory bulbs of the fourth monkey (paralysis for three days) contained the virus, and microscopic examination

revealed no lesions in one bulb while in the other there was evidence of the loss of a few mitral cells with invasion of polymorphonuclear leukocytes in their places; this was not associated with any meningeal or perivascular reaction. In view of the fact that this animal had no preliminary zinc sulfate nasal spray and because paralysis had been present for at least three days, two possible explanations may be advanced: (1) that in this case there was contamination of the olfactory mucosa, with the subsequent involvement of a few mitral cells (the failure to find virus in the nasal mucosa of this monkey cannot be held against this possibility) and (2) that, owing to the relatively long duration, the virus had spread from the medulla to one of the olfactory bulbs. At any rate, it would appear that the elimination of virus on the nasal mucosa in an animal that has succumbed to infection by another peripheral route is either rare or unlikely and that the failure to detect virus in the olfactory bulbs of at least seven of the eight monkeys tested is in good agreement with the other evidence that the virus did not invade the central nervous system by the olfactory pathway.

COMMENT

The evidence presented in this communication shows conclusively that, while mere transitory contact between the normal or injured pharynx or tonsils of monkeys is not enough to produce poliomyelitis, it is possible to infect these animals when the virus in quantities of from 100 to 1,000 minimal cerebral infective doses is injected into the tonsillopharyngeal region and that this region is for some reason more sensitive than, for example, the abdominal cutaneous or subcutaneous tissue. The high incidence of the bulbar type of the disease among these monkeys, along with the other evidence that the virus did not produce the infection by invasion along the olfactory pathway, indicates that after tonsillopharyngeal injection the virus progresses along the local peripheral nerves. The high incidence of the bulbar form of the disease among the cases of human post-tonsillectomy poliomyelitis is what one would expect, therefore, if the infection occurred from the throat. If the virus in the human being behaved as it does in the monkey (and there is no definite evidence that such is the case), one would expect that for the development of post-tonsillectomy poliomyelitis the virus would have to be present in the secretions or in the tonsils during the operation and that infection would be facilitated by any procedure involving injections or postoperative suturing. That poliomyelitis virus can occur in the upper respiratory secretions and tonsils of apparently healthy human beings is already known,¹⁶ and, although it is not yet clear whether or not the virus is more prevalent during the summer and early autumn than at other times of the year, it ought to be considered whether or not the season of the high incidence of poliomyelitis is a favorable period for nonemergency operations about the throat and mouth.¹⁷

Office international d'hygiène publique 39:933 [May] 1938) of two cases of paralytic poliomyelitis which followed the extraction of teeth (seven teeth in one case and ten in the other) within six and ten days respectively.

Clinical Notes, Suggestions and New Instruments

LARGE RENAL CALCULUS

M. K. BAILEY, M.D., AND CHARLES A. EBERHART, M.D.
ATLANTA, GA.

In a review of the literature, Kreutzmann¹ of San Francisco lists only eight cases in which single renal calculi weighing more than 300 Gm. were removed. He found that the largest renal calculi the human body is capable of producing have been found at autopsy, at which stones have been discovered weighing from 1,500 to 2,000 Gm. The largest stone in this series was removed by Mylvaganan of England and weighed 1,440 Gm. To this series he adds his case with the successful removal of a solitary stone weighing 650 Gm. with the kidney substance included. Waterworth² removed a renal calculus weighing 1,100 Gm. only to have the patient die five and a half months later of a fungating carcinoma at the operative site, which had been found at operation to originate in the renal pelvis.

REPORT OF CASE

History.—J. E. F., a white man, aged 55, a merchant, admitted to Emory University Hospital Dec. 12, 1936, complained of pain in the left flank. The patient gave a history of having passed a stone a month since he was 3 years of age. These hard yellow stones would soon become friable and crumble to dust when exposed to air. The passage of a stone was invariably preceded by colicky pain in the left flank, and occasionally by bloody urine. In 1908 he passed the largest stone. It was the size of a "field pea," and he required medical attention at that time. He was advised to have the kidney removed but he refused operation. Stones had continued to come at monthly intervals, and their physical characteristics remained unchanged. Although he had continued to work almost without interruption, he stated that a dull aching pain in the left flank had been present for many years. Until of late he had been able to obtain relief at night by sleeping on his left side. In the last two years he had lost 25 pounds (11 Kg.) and for the past three weeks the pain had been increasing in severity. He stated that there was no nocturia except during dysuria accompanying the passage of a stone.

About three years before admission he began to suffer from a "burning" sensation beneath the sternum with periods of freedom from discomfort of as long as two or three months. Sodium bicarbonate was taken for relief of discomfort, which was usually at night and about two hours following meals. There was no hematemesis or tarry stools.

Examination.—The patient was obese, weighing 190 pounds (86 Kg.). The blood pressure was 140 systolic, 88 diastolic. Physical examination was negative except that there was generalized tenderness on the left side of the abdomen. On palpation a hard rounded smooth mass protruded from under the left costal margin to a level of 3 cm. below the umbilicus and as far medially as the parasternal line. The mass descended slightly with inspiration but could not be moved from side to side. There was resistance at the left costovertebral angle. The smooth edge of the liver was palpable for 2 cm. below the right costal margin in the midclavicular line.

The blood count showed a slight secondary anemia and 5 per cent eosinophils. The latter was found to be constant on repeated counts. Chemical analysis of the blood was negative. Urinalysis revealed specific gravity 1.016, reaction acid, albumin 1 plus; centrifuged and stained, it showed many pus cells and many organisms of varied structure.

The vesical mucosa had a granular appearance but was otherwise normal. When the left ureter was catheterized with a No. 5F. catheter an obstruction was met at 28 cm. A yellow cloudy urine dripped constantly, increasing in flow with external pressure on the left flank. A 10 cc. specimen of urine from the left kidney contained 0.1 cc. of sediment, which was

From the Department of Urology, Emory University School of Medicine.

composed entirely of pus cells and no bacteria. Phenol-sulfonphthalein appeared on this side as a faint trace at the end of thirty minutes. A flat roentgenogram revealed a large calcified tumor in the left upper part of the abdomen occupying the position of the left kidney. Its lateral, medial and inferior margins were smooth. The upper border was slightly irregular. It measured 15 by 17 by 13 cm. The opaque catheter in the left ureter entered or passed behind the mass. At the lower border an irregular projection suggested stone in the inferior calix. Attempts to inject the left pelvis with opaque fluid failed. The right kidney was not infected and was of normal phenolsulfonphthalein output; a pyelogram was negative.

Operation.—A left nephrectomy was performed Jan. 14, 1937, under ethylene anesthesia. An incision 30 cm. long was made in the left flank. The perinephric fat was stripped away and the lower pole of an enormous mass composed of kidney substance and stone was exposed. It was free of thick adhesions except on the anterosuperior aspect, where it adhered firmly to the peritoneum. A hard smooth stone could be palpated through the renal parenchyma, the latter being about 1.5 cm. in thickness and showing marked cystic degeneration. The kidney substance had been flattened to such an extent that it covered two thirds of the stone, while the enormously dilated extrarenal portion of the kidney pelvis covered the remaining third. Attempts to deliver the mass into the incision were of no avail, and it was decided to incise the lower pole of the kidney and deliver the stone. Delivery under this plan was more difficult than had been expected, as a good purchase could not be obtained on the stone. Finally it was shelled out, and in the process several of the formed projections in the calices were broken off. The kidney pedicle consisted of a thick fibrous mass of tissue which it was impossible to skeletonize. Kelly clamps were applied to this mass and each portion was cut and tied separately. The entire kidney was removed.

Fig. 1.—Bilateral pyelogram showing enormous calculus of left kidney and normal right kidney.

The patient's blood pressure had dropped to shock level, and 1,500 cc. of physiologic solution of sodium chloride was given intravenously while the incision was being closed. The time required for the operation was two hours and twenty minutes. The patient was given a 600 cc. transfusion of whole blood before leaving the operating room.

Postoperative Course.—Inhalations of carbon dioxide were given twice a day for three days. Twelve hours after operation the patient went into mild shock as a result of blood oozing from the incision, and another 500 cc. transfusion of whole blood was given. Immediately after operation he vomited a

large amount of dark clotted blood, which he continued to do for several days. This suggested either trauma to the stomach or the presence of an old peptic ulcer, and all fluids by mouth were withheld for five days, at which time he began to take a Sippy diet. Three thousand cubic centimeters of 5 per cent solution of dextrose in distilled water was given daily during

Fig. 2.—Appearance of stone. Pieces were broken off during operation.

this period. On the second postoperative day the temperature had reached 101.4 F. and the pulse 140 per minute. Both pulse and temperature returned to normal at the end of the second day and remained so until he was dismissed from the hospital on the twenty-first postoperative day.

An x-ray examination of the upper part of the gastrointestinal tract revealed no ulcer but showed evidence of irritation of the gastric musculature. The stomach was high in the abdomen. Its lower pole dropped into the space previously occupied by the renal calculus.

PATHOLOGIC REPORT

The specimen of kidney and calculus weighed 2,265 Gm. When the operative incision in the kidney was continued upward so as to lay it open, the cortex was found to be almost destroyed and quite uneven, and the calices were markedly dilated and fused into a large saclike pelvis which covered the calculus. Microscopic examination of sections showed the glomeruli to vary considerably in size, some of them being quite small and atrophic and others completely replaced by hyaline changes. Practically all tubules showed varying degrees of albuminous degeneration with some epithelial desquamation. Other areas showed complete fibrous replacement of parenchyma. The stone alone weighed 1,565 Gm. Several fragments had a staghorn appearance and fitted into the calices of the kidney.

Chemical analysis of the stone revealed calcium, magnesium, phosphates, carbonates and a trace of sulfur and oxylates. There were no urates.

COMMENT

It is worthy of note that at the time of cystoscopic, pyelographic and functional study we found a faint trace of phenol-sulfonphthalein appearing from the left kidney mass at the end of thirty minutes. This would seem to indicate that even in the presence of this enormous stone, with resultant thinning out of the cortex, the kidney was still able to secrete some

urine. That the patient was able to supply urinary constituents which go to form stones may account for its reaching this enormous size over a period of many years. The patient lived about one year after this operation in perfect health.

On Jan. 15, 1938, a year and a day after the nephrectomy, a laparotomy was done by a general surgeon, who found a malignant growth suspected to have originated in the head of the pancreas. The gallbladder was drained at that time. The patient died about four weeks after the laparotomy.

As far as we have been able to ascertain from the literature, this is the largest single renal calculus that has successfully been removed.

AN OPERATION FOR PARALYSIS OF THE INTRINSIC MUSCLES OF THE THUMB

N. D. ROYLE, M.D., CH.M., F.R.A.C.S.
SYDNEY, AUSTRALIA

The inability to oppose the thumb to the other fingers owing to paralysis of the intrinsic thenar muscles leads to "flat hand" deformity. This is primarily due to the loss of function in the *musculus opponens pollicis*, but the short flexor and short abductor are also concerned in the production of this deformity. For many years I have been practicing a tendon transplanta-

Fig. 1.—Step 2 of operation.

tion to correct the disability caused by the paralysis and to restore the function of the thumb.

As the thumb had to be drawn to the medial side of the hand, I chose for transplantation the flexor sublimis of the ring finger since this would make the process of education easier.

TECHNIC OF OPERATION

STEP 1.—The skin is opened through the transverse fold at the base of the ring finger. By retracting the skin distally, one can reach the insertion of the bifurcated tendon of the flexor sublimis with a tenotome, with which it is then cut through on each side.

STEP 2.—The sheath of the flexor pollicis longus is opened through an incision at the deep fold proximal to the metacarpophalangeal joint of the thumb (fig. 1).

STEP 3.—An incision is made in one of the transverse folds of the palmar aspect of the wrist. The cut tendon of the

ring finger is then drawn out through this incision. It is passed up the sheath of the long flexor of the thumb and brought out at the incision at the metacarpophalangeal joint of the thumb (fig. 2).

Fig. 2.—Step 3 of operation.

Fig. 3.—Step 4 of operation.

STEP 4.—The attachment of the short flexor and of the *opponens pollicis* is next exposed by dissecting up the skin distally. One part of the bifurcated tendon of the superficial flexor of the ring finger is stitched to the attachment of the

short flexor with the first phalanx in flexion. The other part is stitched to the outer edge of the opponens pollicis with the thumb in opposition. The living suture method is employed; that is, the tendon is the stitch and is sewn into place with the author's living suture needle. This needle has a cutting point; the tendon is actually threaded in the needle and sewn into its new attachment. The tendon of the flexor sublimis may be split so as to lengthen the stitches (fig. 3). The wounds are closed and dressings applied with the thumb strapped in the position of opposition and flexion of the first phalanx. This position is maintained for about ten days, after which active movements are performed.

Fig. 4.—Thumb in opposition after operation.

Fig. 5.—Thumb in abduction after operation.

REEDUCATION

It is easy for the patient to educate himself to use the transplanted tendon, for when he attempts to flex the ring finger the thumb is drawn into opposition to that finger. The superficial flexor muscles of the little finger or of the medial finger may also be used for this operation. Figures 4 and 5 show the result of this transplantation in a typical instance of the deformity.

185 Macquarie Street.

NICOTINIC ACID IN THE TREATMENT OF PELLAGRA REPORT IN A CASE OF MARKED DEMENTIA

C. N. BOGART, M.D., FORREST CITY, ARK.

In recent months there have been quite a few references in the medical literature to the use of nicotinic acid (3:pyridine carboxylic acid) in the treatment of pellagra.¹

Only one of these reports has stressed the fact that the patient had dementia, and it was mentioned as a mild dementia and was present only at intervals.^{1b}

For that reason, it is believed that the report of a case recently observed, in which the patient is still under treatment, will be of interest. Also a comparison may be drawn between the effectiveness of the parenteral and the oral administration of nicotinic acid for pellagrous dementia, as in the case reported here the acid was administered only by the oral route, while in the one previously reported it was administered mostly by the parenteral route.

REPORT OF CASE

Mrs. M. G., aged 59, white, was first seen March 20, 1938. She was in a state of marked dementia, simulating a catatonic type of schizophrenia.² She complained in no way of feeling badly but rather repeatedly stated that she had never felt better in her life. Medical aid was sought because of the rather sudden change in her mental state. She carried on an incessant monologue, became quite violent at frequent intervals and would strike any one within reach or throw any object on which she could lay her hands. Questions directed to her were completely ignored.

1. (a) Relation of Nicotinic Acid to Human Pellagra, current comment, J. A. M. A. 109:1203 (Oct. 9) 1937. (b) Smith, D. T.; Ruffing, J. M., and Smith, Susan Gower: Pellagra Successfully Treated with Nicotinic Acid, *ibid.* 109:2054 (Dec. 18) 1937. (c) Spies, T. D.; Cooper, Clark, and Blankenhorn, M. A.: The Use of Nicotinic Acid in the Treatment of Pellagra, *ibid.* 110:622 (Feb. 26) 1938. (d) Fouts, P. J.; Helmer, O. M.; Lepkovsky, Samuel, and Jukes, T. H.: Treatment of Human Pellagra with Nicotinic Acid, *Proc. Soc. Exper. Biol. & Med.* 37:405 (Nov.) 1937.

2. Sadler, W. S.: Theory and Practice of Psychiatry, St. Louis, The C. V. Mosby Company, 1936, p. 827.

Her past history was irrelevant except for the fact that she had suffered from endemic pellagra for the past six years. Symptoms were noted each year, beginning in the spring and continuing until cold weather. They consisted of loss of appetite, diarrhea, glossitis, drying and discoloration of the backs of the hands and insomnia. During these stages of exacerbation of symptoms she would take pills of ferrous carbonate, Fleischmann's yeast cakes and dilute hydrochloric acid, a regimen of treatment recommended six years before by an internist. As soon as the symptoms abated she would stop all forms of medication.

The present symptoms apparently began in January 1938, when she again noticed a diminution in appetite, insomnia and tingling and burning of the feet and legs as high as the knees. About this same time members of the family noticed that she was not quite normal mentally. Her condition gradually became worse, until there was a complete loss of appetite, vomiting of practically everything taken into the stomach, marked insomnia and frequent attacks of severe depression. The day she was first seen she suddenly became violent and exhibited all the signs of complete loss of the mind.

Owing to her violent mental state examination was extremely difficult. An exacerbation of pellagra was found to be present. The dorsa of both hands were very dry and red; some pigmentation from a preceding involvement was present. The tongue and buccal mucosa were slick and red. The skin over the entire body was dehydrated and very rough. Superficial sensations in the feet and legs were apparently diminished. It was impossible to determine the activity of reflexes because of the violent motions and complete lack of cooperation. The results of physical examination were otherwise negative except for observation of a slight irregularity of the pulse and a blowing systolic murmur over the base of the heart. The blood pressure was 142 systolic, 94 diastolic. An electrocardiograph was not available. Examination of the blood showed slight anemia: red cells 4,250,000, hemoglobin content 85 per cent (Sahli), and white cells 6,800: 60 per cent polymorphonuclear leukocytes, 38 per cent lymphocytes, 2 per cent eosinophils. The specimen of urine submitted for analysis was highly colored, acid, with a specific gravity of 1.032, albumin 2 plus and no sugar; under the microscope pus cells, red blood cells and coarsely and finely granular casts were observed.

An attempt was made to institutionalize the patient in a nearby medical center but this was not successful, so treatment was begun at home and consisted of administration of liver extract and vitamin B₁. All medication and fluids were, of necessity, given parenterally. One of the barbiturates, in doses of 3 grains (0.2 Gm.), was given every three or four hours for the mental condition.

This routine was followed for seven days, during which time the patient was constantly restrained. Attempts were repeatedly made to give some fluids and food by mouth, and after the fourth day some of these were partially successful. From the fourth through the eighth day she was given about 30 Gm. of dried brewers' yeast (all that could be given) daily in addition to the other treatment.

After seven days of this treatment no improvement could be noticed. The physical signs and mental symptoms were just the same as at the beginning of treatment.

On the eighth day treatment was begun with nicotinic acid, administered orally, in doses of 100 mg. five times a day, as recommended by Spies, Cooper and Blankenhorn.^{1c}

Twenty-four hours after the administration of nicotinic acid was started she asked for a drink of water, the first time she had asked for anything in nine days. Twelve hours later she would take food placed in her mouth. This was the first indication of any improvement whatever.

Forty-eight hours after the first dose there was definite improvement, both in her physical appearance and in her mental symptoms. She still talked at random and occasionally was violent, but the improvement was easily seen. She would frequently ask for water and would attempt to take all foods given her. At this time the use of liver and vitamin B was stopped, and the brewers' yeast was increased to 180 Gm. a day.

Seventy-two hours after the beginning of treatment with nicotinic acid the mucosal and cutaneous signs were practically

nil, and only at infrequent intervals was there any indication of mental restlessness. She had slept well the preceding night without the aid of the barbiturates. She said she was hungry and that all foods tasted good for the first time in over two months.

On the fourth day of treatment she became perfectly rational; cutaneous signs had disappeared except for a few patches of pigmentation on the backs of the hands. At the time of this report, seven days after the administration of nicotinic acid was started, she has been rational for seventy-two hours without once exhibiting symptoms of depression or dementia.³ Her facial expression is normal, the skin is normal except for slight patchy pigmentation, the tongue is only slightly red on the borders, and her appetite is excellent. The blood pressure, pulse and murmur are the same as at the first examination.

Examination of the blood reveals: red cells 4,550,000, hemoglobin content 94 per cent (Sahli), white cells 6,500; 60 per cent polymorphonuclear leukocytes, 40 per cent lymphocytes.

On analysis the urine is normal in appearance, acid, with a specific gravity of 1.018, no albumin and no sugar. Under the microscope occasional pus cells and casts are observed.

It is believed that in this case full credit for recovery is due to the treatment with nicotinic acid.

COMMENT

As was stated, the patient was started on a dose of 500 mg. of nicotinic acid daily in five doses of 100 mg. each. No effects of the drug were noticed which could be considered side effects or contraindications; not even the sensation of heat and redness of the skin was noticed, as is reported in most cases. To determine whether any symptoms would develop after prolonged administration, this patient was kept on a daily dose of 500 mg. until a total of 8 Gm. had been taken. Then the dose was dropped to 300 mg. daily until another 6 Gm. had been taken, making a total of 14 Gm. over a period of two months. On only two occasions were redness and warmth of the skin noticed; this condition lasted for about fifteen minutes each time and caused the patient no particular discomfort.

After the first week of the administration of nicotinic acid the patient has been on a full pellagra-preventive diet, with dried yeast (from 120 to 180 Gm. daily).

Physical examination May 22 showed that the patient was a normal healthy woman without any indications of pellagra or dementia.

From observations on this one case it appears that the toxicity, if any, of nicotinic acid is negligible. It also appears that by the use of this drug in an advanced case of pellagra there is a much better chance of placing the patient in a position to take a pellagra-preventive diet than would otherwise exist. Is it not possible that the stomatitis, intestinal cramping and diarrhea bring about a dislike for food because of the difficulty in taking it and thereby set up a vicious circle? It is not likely that any one would look on nicotinic acid as a substitute for food. In the cases so far reported it brings about a rapid abatement of symptoms, so that these patients can be placed on the proper diet.

Such recurrences could hardly be attributed to the non-specificity of the drug. Some of these persons are alcoholic addicts who are going to take whisky even to the exclusion of necessary foods; there are others who are unable to get the proper foods because of their standard of living. Some patients will, no doubt, have relapses, it being assumed that the cause of pellagra is dietary deficiency.

SUMMARY

1. A woman with severe pellagrous dementia recovered after seven days of treatment with nicotinic acid in doses of 100 mg. five times a day.

2. Apparently a drug has been found which will greatly simplify the treatment of pellagra. Since the cost of the medication is so small, any one suffering from pellagra should be able to get it.

210 North Izard Street.

3. An additional report of the use of nicotinic acid for pellagra has just appeared in *THE JOURNAL*. (Spies, T. D., and Aring, C. D.: The Effect of Vitamin B₁ on the Peripheral Neuritis of Pellagra, *J. A. M. A.* 110:1081 [April 2] 1938). The dementia of one of the patients discussed in this article was more marked than that of the one originally referred to^{2b} but still was of much less degree than the one here reported.

Special Article

PHYSIOLOGY AND PATHOLOGY OF VITAMIN D

ALFRED T. SHOHL, M.D.

BOSTON

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

Vitamin D prevents or cures rickets. Until recently this factor was thought to be a single substance. The active compound formed by the irradiation of ergosterol was considered identical with the antirachitic agents present in natural products or formed in animals or foods by ultraviolet irradiation. It was found, however, that different sources of vitamin D might have different relative values, depending on whether the products were tested with rats or with chickens. It was found also that several different sterols, carefully purified, could be activated by various methods. The multiple nature of vitamin D thus became established, and Bills recently has described ten different substances which are capable of exerting a vitamin D effect. As more information becomes available regarding the chemical nature of the different forms of vitamin D, there may be afforded a clearer understanding of the physiologic and pharmacologic aspects of each active substance. At the present time, however, vitamin D can be detected only by its effect in the prevention or alleviation of rickets. Thus it happens that different sources of vitamin D have qualitatively the same effect on the animal body.

RICKETS

Rickets is a condition made manifest by defects in the calcification of growing bones. It may be recognized by roentgenologic examination of the bones or, in experimental animals, by chemical analysis of the bone ash, by histologic examination or by other methods. The court of last resort is the histologic picture of the bone.

The sequence of events in the production of normal and of rachitic bone has been epitomized by Wolbach.¹ Growth in the length of the long bones occurs by endochondral formation of bone. In the normal tibia of the growing rat, for example, the epiphyseal cartilage at the upper end of the shaft is a narrow plate. This is firmly supported by bone, in the form of transverse trabeculae or a thin fenestrated plate, on the epiphyseal side, and it is uniformly penetrated by capillaries on the diaphyseal side. Growth occurs by the continuous proliferation of cartilage cells, which are arranged in orderly columns on the epiphyseal side, and by the simultaneous degeneration of the matured cartilage cells on the diaphyseal side. In the spaces left by the degeneration and disappearance of the cartilage cells there appear capillaries and bone-forming cells, or osteoblasts.

From the Department of Pediatrics of the Harvard University Medical School and the Infants' and Children's Hospitals.
1. Shohl, A. T., and Wolbach, S. B.: Rickets in Rats: XV. The Effect of Low Calcium-High Phosphorus Diets at Various Levels and Ratios upon the Production of Rickets and Tetany, *J. Nutrition* 11: 275 (March) 1936.

These are responsible for the deposition of the bony matrix. The growth of bone by endochondral formation of bone, according to Wolbach, is achieved "by a continuously retreating gap in the continuity of tissues, maintained on the epiphyseal side by continuous renewal of cartilage cells and on the diaphyseal side repaired by vascular outgrowth comparable to repair of any defect of tissues by the process of organization or granulation tissue formation. In normal growth there presents on the diaphyseal side of the narrow cartilage a continuous layer of clear or empty cartilage cells forming an almost straight line."

The first histologic evidence of rickets is the cessation of the degenerative sequences of the cartilage cells. The layer of clear cells does not form, and consequently there is no ingrowth of capillaries and osteoblasts. If the degree of rickets is slight, there is a moderate increase in the width of the epiphyseal cartilage. Because the cessation of degenerative sequence in the cartilage cells does not occur simultaneously in all the affected cells, the epiphyseal cartilage presents an irregular border on the diaphyseal side. The width of the cartilage increases because of continued activity of the proliferative zone and the survival of cells on the diaphyseal side.

After the cessation of degenerative changes in the cartilage cells of the rachitic bone, calcification of the cartilaginous matrix ceases, and osteoid material accumulates around the capillaries of the diaphysis. In advanced rickets some changes occur that are probably brought about by the pressure of weight bearing. The uncalcified cartilage of the diaphyseal border often is stratified transversely in places, and the osteoid material, which is also uncalcified and which increases in amount with the duration of the dietary deficiency, becomes molded. In long-continued rickets there may be a disappearance of the cancellous bone of the diaphysis and a marked resorption of cortical bone. "The degree or severity of rickets may be recorded on the basis of the prominence of anatomical changes. Obviously two factors enter into the production of the pathological picture; the duration of the deficient diet and the degree of the deficiency."¹

The changes in the bones in rickets result in those gross manifestations which are recognized clinically;² namely, enlargement of the wrists, knees and ankles, bowed legs, beading of the ribs and the rachitic rosary, Harrison's groove and craniotabes.

When vitamin D is given to rachitic animals, calcification begins again at the line of provisional calcification. The first histologic evidence of repair is the presence along the diaphyseal border of degenerated cartilage cells. This effect is visible at the end of twenty-four hours and is accompanied by extensive vascular penetration within forty-eight hours. The penetration of blood vessels permits the deposition of the bone-forming salts. There is thus produced the so-called line test for healing. The mass of irregular cartilage cells becomes arranged into short, orderly, parallel columns of a few cells. Osteoid material is no longer formed. A remarkable degree of repair takes place, but for a long time the expert pathologist can detect traces of the former abnormality.

It has now become generally recognized that there is no fundamental pathologic condition in the rachitic

bone which prevents its calcification. Shipley³ reported in 1924 that slices of rachitic bone and cartilage became calcified when placed in normal blood serum. Later Shipley, Kramer and Howland⁴ showed that suitable solutions of inorganic salts would bring about a similar result. This has been confirmed by Robison and Soames.⁵ Further, as shown by Harris,⁶ there is no reason to believe that vitamin D acts directly on bone cells to promote calcification. The action of vitamin D, instead, is so to alter the body fluids that bone salts may be incorporated into the growing bone. Rickets may be regarded as a fault in the metabolism of calcium and phosphorus. In this sense, rickets is the cause and not the result of the bony lesion.

CHEMISTRY OF CALCIUM AND PHOSPHORUS PRECIPITATION

Whatever may be the cause of the defect in metabolism which leads to rickets, the pathogenesis lies in the condition of the Ca^{++} and $(\text{PO}_4)^{---}$ in the blood serum.⁷ Here is found the material available for excretion by the intestine or kidney or for deposition in bone or other tissues of the body. It has been mentioned that minerals will precipitate in rachitic cartilage in vitro either in normal serum or in properly constituted inorganic solutions. This does not imply that the formation of bone is an inorganic process. It takes place in the living cell, and the proper type of cartilage degeneration is essential to the entrance of the blood vessels. What takes place in the space between the cells is quite obscure, but certainly the proper inorganic environment is essential to deposition. It can best be expressed in physiochemical terms.⁸ Only when the adequate concentration of calcium, phosphate and carbonate ions is present can precipitation of the salt take place. This complex salt is a dahllite, $n\text{Ca}_3(\text{PO}_4)_2\text{CaX}$ in which the n varies between 2 and 3 and the X may be CO_3 , OH or F . It may be regarded as a solid solution of CaCO_3 in $\text{Ca}_3(\text{PO}_4)_2$. The ratio of two mols of $\text{Ca}_3(\text{PO}_4)_2$ to one mol of CaCO_3 is practically constant for adult bone, which by analysis gives 12 per cent CaCO_3 and 88 per cent $\text{Ca}_3(\text{PO}_4)_2$.

By the use of a frog heart method for the determination of ionized calcium, McLean and Hastings⁹ were able to show that the larger part of the serum calcium was combined with protein. Of the usual 10 mg. per hundred cubic centimeters of serum, about 4.5 mg. or 1.1 millimols is ionized. According to their calculations not over 5 per cent of the total calcium can be in diffusible nonionized form.

The composition of the salt precipitated from a solution containing Ca^{++} , $(\text{PO}_4)^{---}$ and $(\text{CO}_3)^{--}$ gradually increases in CO_2 content. Logan and Taylor¹⁰ have shown that the solubility product varies with the amount of substrate present and that a higher concentration is necessary to initiate the formation of the precipitate than to permit its subsequent formation.

Thus, although the concentrations of these ions at the site of calcification are as yet unknown, the advances that have recently been made in the quantitation of Ca^{++} , $(\text{PO}_4)^{---}$ and $(\text{CO}_3)^{--}$ and the solubility product constant necessary for precipitation in bone bring chemical explanation much closer.

PHOSPHATASE

The enzyme phosphatase discovered by Robison¹¹ has the property of splitting organic phosphorus compounds such as hexose phosphate into inorganic phosphate. This enzyme occurs in largest amount in the cartilage but appears also in the kidney, bowel and blood serum. Just what the function of phosphatase in the serum may be is not known, for the acid soluble phosphorus is present almost entirely as inorganic phosphate. Kay¹² regards it as a "leakage" from tissues of higher content. It may deal with the correction of phosphates by way of the kidney or bowel or the metabolism within the cell. Such a liberation of phosphate may be a step in the mechanism of carbohydrate metabolism or in muscle function. Certainly, if phosphorus esters were present in bone tissue, the local increase of inorganic phosphate would be an important step in the precipitation of calcium phosphate. However the phosphatase acts, there is no question that in diseases of the bone, especially resorptive ones in which osteoblastic activity is increased, the phosphatase of the serum is increased. Such is the case in rickets. Its increase is perhaps the first definite evidence of development of the rachitic condition, antedating roentgenogram changes and alterations in the blood serum phosphate. The content is high in active rickets. When vitamin D is administered it decreases toward normal, but more slowly than the other values; the phosphatase may not reach a normal content for several months after there is evidence of healing.¹³ The increase of phosphatase in low phosphorus rickets thus acts as a protective mechanism.

HYPERVITAMINOSIS D

When huge excesses of vitamin D are given, there results a definite pathologic condition called hypervitaminosis D.¹⁴ It is an exaggerated form of the physiologic or therapeutic effect of this vitamin. The calcium and the phosphate level in the blood are raised above normal. Calcification takes place at an increased rate, so that on roentgen or histologic examination the deposition of minerals at the provisional zone of calcification is usually dense. When the dose is sufficiently large, about a thousand times the therapeutic dose, the deposition of minerals at the epiphyses is made at the expense of that in the shaft. The balances of calcium and phosphorus become negative.¹⁵ Metastatic calcification now takes place. The organs most affected are the tubules of the kidneys, blood vessels, heart, stomach and bronchi. There is evidence of irritation and degeneration in these tissues and in the liver. Under these conditions the animals lose weight rapidly, have intense diarrhea and die in from five to fourteen days.

With smaller doses death comes later or the animal survives. Animals which live show the lesions described at least six months afterward. Healing of rickets takes place with diets which are deficient in either calcium or phosphorus. Calcification is less severe and more delayed, but the degenerative changes are as severe as those found in animals fed a normal diet.

RELATION OF RICKETS TO GROWTH

Body growth and development are coordinated with, and limited by, skeletal growth. Paucity of minerals necessary for the formation of the bones retards not only the development of the skeleton but that of the entire body. Because bone salts are predominantly salts of calcium and phosphorus, it is not surprising that the ingestion, absorption, assimilation and utilization of these two elements are the principal factors which determine the development of the bone. Osborne and Mendel¹⁶ showed that calcium or phosphorus could be the limiting factor of growth. Shohl and his collaborators¹⁷ extended their studies to show that even with liberal additions of vitamin D to diets restricted in phosphorus, growth was limited to as much as 40 per cent of the normal.

It has long been a clinical dictum that the manifestations of rickets are proportional to the growth of the infant—"no growth, no rickets"—but from studies of experimental rickets it is obvious that the condition may be present without increase in weight or even with a decline in weight. In no case of experimental rickets is the growth as great as normal. With an otherwise adequate diet it is primarily the utilization of calcium and phosphorus which determines the rate of growth, and it is the interrelation of calcium and phosphorus and vitamin D which determines the development or the cure of rickets.

RELATION OF RICKETS TO DIET

The successful production of experimental rickets depends on the proper regulation of the calcium and phosphorus of the diet in the absence of vitamin D. In children and in some experimental animals, e. g., dogs,¹⁸ a deficiency of vitamin D alone, without great distortion of the diet, is sufficient to produce rickets. With rats the calcium and phosphorus of the diet must be restricted or fed in unusual proportions. Complete reviews of the earlier literature may be found in the works of Goldblatt,¹⁹ Hess,² György² and Gubner.²⁰ Briefly, it may be recalled that McCollum and his collaborators²¹ investigated a wide variety of diets and obtained their best results with a diet of high calcium and low phosphorus content. They also reported success with low calcium and high phosphorus diets, although with these the bony lesions differed slightly from those which are found in children. When the calcium and phosphorus were about equal, they did not obtain rickets in rats. Sherman and Pappenheimer²² and Steenbock and

Black²³ also used high calcium and low phosphorus diets. With a low calcium and low phosphorus diet, Korenchevsky reported that rickets was not obtained, but the same diet with added calcium salts was shown by Goldblatt²⁴ to cause marked rickets. Thus it became a firmly fixed idea that the rachitogenic properties of a diet depend on the imbalance or disproportion between calcium and phosphorus. Experimental diets of this type, especially the Steenbock and Black No. 2965 (which is chemically similar in composition to the McCollum No. 3143), consist of 76 per cent corn, 20 per cent gluten flour, 3 per cent calcium carbonate and 1 per cent sodium chloride. The calcium content is about 1.2 per cent and the phosphorus about 0.25 per cent. The ratio of calcium to phosphorus is from about 4:1 to 5:1. The results obtained were so satisfactory that these diets became the standard rations for experimental production of rickets and also for the vitamin D assay. The necessity for constant and standard rachitic animals tended to discourage the study of other diets.

More recently, the experimental diets used in the production of rickets were systematically investigated over a wide range of possible variations by Brown and others,²⁵ Querido²⁶ and Shohl.¹ This was made possible by the addition of varying amounts of salts of calcium and phosphorus to a basal diet of corn and gluten. The lower limit approximated calcium and phosphorus starvation, and the upper limit, which was obtained by feeding a mixture which contained 20 per cent salt mixture, constituted all the calcium or the phosphorus that the animals would eat. It thus became obvious that not only the ratio of calcium to phosphorus but the absolute amount of each at that ratio determines the rachitogenic properties of the diet. As the ratio of calcium to phosphorus was increased for a given level of phosphorus, rickets became more intense (for low phosphorus diets). As the absolute amounts were diminished, the degree of rickets became more intense, not only for the high calcium-low phosphorus diets and the low calcium-high phosphorus diets but for the low calcium-low phosphorus diets. The last group of diets fell in the zone of calcium to phosphorus ratio of 2:1 to 1:2, which was previously considered to be "normal" or, at least, was not considered to be associated with rickets. In all cases in which the amounts of calcium and phosphorus were sufficient and the disproportion not too great, normal bones were produced and extra vitamin D was not needed.

Because both calcium and phosphorus are necessary to form bone, theoretically any substance which prevents the adequate utilization of either should lead to abnormalities in bones and possibly to rickets. Work on low calcium diets in this regard is lacking. With diets low in phosphorus, not only does a high calcium level prevent adequate utilization of phosphorus but the other metals which form insoluble phosphates (except barium, which is too toxic even for experimental trial)

cause rickets. In this list are beryllium,²⁷ magnesium,²⁸ strontium,²⁹ iron,³⁰ lead³¹ and thallium.³²

RICKETS AND THE ACID-BASE CONTENT OF THE DIET

The metabolism of vitamin D not only is interrelated with calcium and phosphorus but is dependent on the acidity of the diet. It has long been believed that acidity is associated with rickets and alkalinity with tetany. The acidity of the food can be considered both from the point of view of the true acidity, or hydrogen ion concentration, and from the stoichiometric point of view, in which consideration is given to the excess of mineral acids or bases. The true acidity exerts its effect principally on absorption from the intestinal tract. On the acid side the absorption of calcium and phosphorus is facilitated; on the alkaline side the absorption is retarded or inhibited. The potential acidity or alkalinity of a diet depends on the amount of alkaline elements, calcium, magnesium, sodium and potassium, as compared with the amount of acid elements, chlorine, sulfur and phosphorus. Acid foods, meaning those which have an excess of the acid elements, increase the excretion of calcium and phosphorus. Foods which are potentially alkaline tend toward diminished excretion and hence to a greater retention of calcium and phosphorus in the body. The total effect is therefore the result of the true and the potential acidity of the food.

An advance has recently been made by Hamilton and Schwartz,³³ who were able to separate and combine the effects of the diet on absorption and metabolism. By the use of a diet which provided an excess of organic acid and an alkaline ash, they facilitated both absorption and retention of calcium and phosphorus. Diets which were alkaline in reaction and which had an acid ash hindered both the absorption and the retention of calcium and phosphorus. These workers were able to convert rachitogenic diets into normal diets by the addition of organic acids and alkaline ash. They were able also to produce rickets by adding alkalis plus acid ash to normal diets. The former diets contained additions of tartaric acid and sodium tartrate, and the latter, additions of ammonium carbonate and ammonium chloride. Shohl³⁴ found that these effects were not due entirely to the acid-base properties of the diet but were due also to a specific organic acid effect, in which the tartrates were involved. The citrate ion showed even more pronounced effects. Additions of citric acid plus alkaline residue to rachitogenic diets were found to prevent or cure rickets. This result was obtained not with a single type of diet but with several widely different combinations of calcium and phosphorus.

UTILIZATION OF CALCIUM AND PHOSPHORUS

The diets which produce rickets exert a profound influence on the body economy. This is evidenced by

their effect on the blood serum content of calcium and of inorganic phosphate. In general the composition of the blood serum in this respect reflects the composition of the intake. High calcium and low phosphorus rachitogenic diets are associated with a low inorganic phosphate content in the blood serum, a condition similar to that found in human rickets and hence utilized extensively for studies in experimental rickets, especially for vitamin D assays. Similarly, a low calcium and high phosphorus intake is associated with serum calcium values which are at or near the tetany level. In such cases the serum phosphorus is elevated roughly in proportion to the intake.

The absolute amounts as well as the ratio of the calcium to the phosphorus determine the content of these elements in the blood serum. At any ratio of calcium to phosphorus in the food, as the absolute amounts increase the serum calcium and phosphorus, respectively, increase also. When vitamin D is given, the blood serum values tend to become normal, regardless of the type of diet.³⁵

The effect of the acid-base content of the diet on the composition of the blood serum seems to be secondary to the ratio and level of calcium and phosphorus of the diet. In selected cases, however, it can be shown that acid ash diets produce a blood picture which tends toward rickets and that alkaline diets tend to cause healing.

It has been a favorite thesis of Freudenberg and György³⁶ that rickets is associated with an acid metabolism and tetany with an alkaline one. György has relied on determinations of the ammonia in the urine, a reliance which has been seriously questioned by Morris, Ford and Graham.³⁷ György also has cited early work of Hodgson,³⁸ who reported that greater doses of sodium bicarbonate were required to make the urine alkaline for rachitic children than for normal children. However, the classic rickets-producing diets are alkaline, and tetany may be induced even with acid phosphates. In neither clinical nor experimental rickets, nor in rachitic tetany, is there a definite alteration of the acid-base equilibrium of the blood.

After material has been absorbed from the intestine, it must take one of three paths. It may be subsequently excreted by the kidneys, it may be reexcreted into the intestine or it may be deposited in the tissues. Thus the amount of material in the stool represents both unabsorbed material and that which has been reexcreted through the intestine. Further, the calcium and phosphorus which are excreted may come either from that ingested or from that which is stored in the body. Calcium is excreted almost wholly by the bowel, about 90 per cent in infants and about 60 per cent in adults, and the major portion of the phosphorus may be excreted either by the kidneys or by the intestine. An excess of calcium causes a reduction in the urinary phosphorus;³⁹ an excess of phosphorus results in low urinary calcium values.⁴⁰ Acid increases the urinary

excretion of calcium and phosphorus,⁴¹ and alkali increases the proportion found in the feces. Parathyroid hormone⁴² also causes an increased excretion of calcium and phosphorus in the urine.

In clinical rickets there is an increased excretion of calcium in the feces, and the amount in the urine, normally small, is further decreased. The elimination of phosphorus in the feces is also markedly increased. As was first shown by Schabad,⁴³ it may exceed the fecal calcium. In infantile rickets both the calcium and the phosphorus balance are subnormal. They may be negative in severe rickets but usually are not.⁴⁴

The effect of the administration of vitamin D is striking. Not only is the blood serum restored to its normal content of calcium and inorganic phosphate, but the metabolism is markedly altered. The amount of calcium and of phosphorus in the feces become reduced, while the amounts in the urine increase. The retention is also increased, so that one sometimes refers to the phenomenon as an increased "net absorption" of calcium and phosphorus.⁶

In experimental rickets the retention values reflect the amounts of calcium and phosphorus in the diet. When vitamin D is given, the blood serum values approach the normal. The absorption is affected similarly to that of infants, but the absolute retentions or the ratio of the calcium retained to the phosphorus may not be restored to normal. High calcium and low phosphorus diets result in high calcium and low phosphorus retentions, vitamin or no vitamin.¹⁷

Vitamin D and Parathyroid.—The relationship of vitamin D and parathyroid hormone has been intensively investigated.⁴⁵ It was suspected that their actions were interdependent, but it now seems clear that, although both raise the level of calcium and of phosphorus, the action of each is quite different. Parathyroid acts more specifically on the serum calcium. When it is given for parathyroprivic tetany the serum calcium level is dramatically raised and the phosphate content may be depressed. Only when toxic doses are given is the effect in raising the phosphate level marked. Vitamin D has its most spectacular action in raising a low serum phosphate level in rickets. As previously stated, in toxic doses it increases the calcium content above normal and may depress the phosphate content if it is high. Parathyroid seems to act principally by withdrawal of calcium from the body; vitamin D, by increased absorption, or diminished reexcretion into the bowel. The toxic effect of parathyroid is decalcification; that of vitamin D, hypercalcification.

In rickets, as originally shown by Erdheim and repeatedly confirmed, the parathyroid glands enlarge

and the cells hypertrophy. This occurs in human beings, rats, rabbits and fowl. Hamilton and Schwartz⁴⁶ were able to demonstrate an increased hormone content in the serum of rachitic rabbits. This overactivity of the parathyroid glands is not the cause of rickets but is caused by rickets. The reaction is apparently a defense mechanism of the body to preserve the normal level of serum calcium, so essential to the body economy. As far as rickets is concerned, this hyperfunction of the parathyroids intensifies rather than ameliorates the condition. Shelling, Asher and Jackson,⁴⁷ Collip and his co-workers⁴⁸ and Waltner⁴⁹ found that injection of the hormone exaggerated the rachitic process in rats. Hoag and his associates⁴⁹ and Fine and Brown⁵⁰ found that it retarded the healing. Such action depends on the type of diet. With a normal diet, not rickets but osteitis fibrosa cystica results. Further, Pappenheimer⁵¹ and Shelling⁵² both stated that it is more difficult to produce rickets after removal of the parathyroids.

OTHER PHASES OF VITAMIN D METABOLISM

The metabolism of calcium and phosphorus has been discussed in relation to vitamin D. Certainly the metabolism of magnesium and of iron also must be affected. The relation to carbohydrate metabolism has been hinted at in relation to phosphatase. The fat metabolism also is interrelated to the problem. If fat is not utilized, the fatty acids are excreted in the intestine, where they form calcium soaps and thus interfere with the calcium and phosphorus economy.⁵³ In such conditions as fatty diarrhea and celiac disease, rickets may intervene. Rickets thus caused is amenable to vitamin D therapy.

A great deal has been written on the relation of dental caries to vitamin D, especially by May Mellanby⁵⁴ and the English workers. Insofar as the teeth are part of the bony structure, the relation to vitamin D seems straightforward. However, the explanation of the underlying physiologic and pathologic process is still clouded, and the multiplicity of therapies indicates that vitamin D is not the sole factor.

For the pregnant or lactating woman faulty diet and paucity of vitamin D present a real problem. There is no doubt that the offspring may come into the world with poorer reserves of antirachitic factors. The mother and infant show symptoms of calcium and phosphorus deficiency.⁵⁵ Congenital tetany and early rickets are found when searched for. The fact that vitamin D is excreted in the milk⁵⁶ suggests the possibility of prophylaxis against rickets in the infant through ingestion of vitamin D by the mother.

Renal rickets is associated with damaged kidney and upset of the phosphate excretion, often complicated by acidosis.⁵⁷

Finally, intractable rickets has been reported, for which the therapeutic effect of vitamin D could be obtained only when the dose was multiplied many thousand times. These are but a few of the problems the solution of which lies in the future.

SUMMARY

To summarize known facts, it may be stated that the study of the physiology and pathology of vitamin D has advanced to the point where it is recognized that:

The metabolism of vitamin D is closely related to the composition of the diet, especially the content of calcium and of phosphorus and the acid-base value.

The metabolism of vitamin D is related to the parathyroid hormone, phosphatase and other factors.

The main action of vitamin D is to increase the absorption of calcium and phosphorus or to diminish their intestinal excretion.

When the concentration of Ca^{++} and $(\text{PO}_4)^{---}$ in the body fluid surrounding the degenerating cartilage cell as measured by the state in the blood is sufficiently great, deposition of salts in growing bone occurs.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

AUDI-EAR NOT ACCEPTABLE

Manufacturer: American Earphone Company, 10 East Forty-Third Street, New York.

The Audi-Ear is a transparent reflector placed next to the ear. The instrument is recommended for the moderately hard of hearing. It operates without a battery. The unit is approximately $1\frac{3}{4}$ inches long and one-half inch thick. A molded earpiece may be used with the device to hold it firm against the ear, in which case a head band is not necessary. It may be carried in one's pocket when not in use, as it comes in a carrying case which protects it against breaking. A single Audi-Ear may be used in either the right or the left ear. Two of these devices may be used only when the hearing impairment in the two ears is similar. The firm states that the unit may be used on trial for ten days and if unsatisfactory the cost price will be refunded except for a slight fee for trial.

The unit was investigated under conditions acceptable to the Council. Two patients were tested. One had an approximately uniform hearing loss of 30 decibels from 64 to 8,192 cycles, and the other had a uniform loss of approximately 45 decibels over the same frequency range. The former had normal bone conduction, while the bone conduction of the latter was slightly below normal. Only the hard-of-hearing person with the 30 decibel loss obtained any value from the use of this device. The improvement was noted as a slightly more natural quality of speech rather than an increase in loudness or intelligibility. Apparently it is of value to only a very small percentage of hard-of-hearing persons, those with slight losses who have more loss for the high frequencies than the low. It is roughly equivalent to cupping the hand behind the ear.

In the light of available evidence, the Audi-Ear Hearing Aid is of value to relatively few hard-of-hearing persons. The advertising matter contains misleading statements, such as "Does for your hearing what eye-glasses do for your sight." Hard-of-hearing persons may purchase the unit believing that it will be of real benefit. Influenced by the exaggerated claims made in the advertising matter, the public may be misled as to its actual value. The Council on Physical Therapy voted not to accept the instrument in the interest of the welfare of the public.

THE COLUMNISTS COMMENT ON THE ARNOLD PRONUNCIAMENTO

Elsewhere in this issue (p. 623) appear editorials published in various newspapers relative to the pronunciamento of Thurman Arnold, who proposes to determine whether or not the American Medical Association is a monopoly. Seldom has an action taken by the Department of Justice aroused the public interest and attention developed by this action. In addition to the editorials which have appeared in the newspapers, practically every one of the columnists syndicated in newspapers throughout the country has had something to say on the subject.

Paul Mallon, widely circulated by King Features Syndicate, in his column *News Behind the News*, after describing the case and stating that if the American Medical Association is a monopoly so is the American Bar Association, says that this suit—

would simply mean the Justice Department is misnamed and has become instead a prosecution department to enforce, not alone the law, but social and economic theories.

Mr. Mallon also indicated that application of this principle would mean that newspaper correspondents might object because some of them cannot get into the press galleries of Congress, and the attendance on the President's press conferences is also strictly limited. Those who can get in have a great commercial advantage over those who cannot.

Mr. Hugh Johnson feels that the attitude of the American Medical Association in resisting cooperatives is "heading straight for the dog-house of public disfavor" but he is inclined to think that the Department of Justice has not picked out the way—

to bring about the desired end. . . . It is a slick, novel and sort of smart-aleck use of a 40-year-old law for a purpose which nobody ever before believed that it was intended.

David Lawrence, widely syndicated, feels that—

the doctors have a society which is as much entitled to protection under the Wagner Relations Act as any other association of service workers.

After explaining his view that the Department of Justice has intervened principally to help the Group Health Association, Inc., Mr. Lawrence says,

The attempt to drag the antitrust laws into a controversy over what is or is not proper medical care is a piece of amazing political stupidity, but it is another example of how the zealots in the administration, with the full approval of President Roosevelt, are manipulating the laws of the United States to gain the goals of their so-called social experiments.

Mrs. Walter Ferguson, after explaining the nature of the controversy in Washington, says:

The average layman holds himself aloof from the controversy about his welfare now raging between the federal government and the American Medical Association.

If he is a middle-class citizen, he considers himself a martyr and is fond of saying that only the very rich and the very poor receive any consideration from doctors—although I doubt whether he would be willing to exchange places with the poor.

If we are honest, we must admit that our attitude toward the doctor has always been irritable and without consistency. We're ready to spend money on everything except our health. Most families will make any sacrifice to buy an automobile on the instalment plan, while they feel much aggrieved if they have to invest monthly sums to pay for medical attention which may have kept one of them out of the grave.

In the *Baltimore Sun* Mr. Henry L. Mencken says:

A defect common to all the plans so far proposed is that they are confined to employed persons and offer no aid to the unemployed. The latter are thus thrown on the free clinics, which are mainly manned by doctors who get nothing for their work.

This puts a very heavy burden on the medical profession, and there are doctors who begin to find it almost intolerable. Proposals have been made that the federal government offer them some remuneration, and no doubt this will be done as soon as the New Deal wizards can get around to it.

But whether the doctors will accept remains to be seen. Most of them are unalterably opposed to going on the public pay roll and so submitting their work and their fortunes to the will and whim of politicians.

Their opposition is hardly likely to be lessened by the fact that all the Communist organs have begun a violent campaign against them, denouncing them as sharks and scoundrels. Or by the fact that the New Deal has now joined in.

A newspaper columnist named Jay Franklin, who has repeatedly attacked the American Medical Association since he first appeared on the newspaper horizon and who endeavors to identify the Editor of *THE JOURNAL* as personally responsible for every policy of the American Medical Association, devotes most of his discussion to a further attack. It is impossible to find anything in his column sufficiently sensible to merit quotation. He writes as though authoritatively without having made the slightest apparent effort to find out the facts. In contrast, Bugs Baer, in a few succinct sentences, puts his finger squarely on the political motives involved in the attempt to make medical care the issue in future political campaigns:

The doctors don't approve of the federal health plan subject to a prescription by thirty-six states. A Democratic pharmacist deciphering a Republican doctor's diagnosis might mix in too much filibuster and not enough relief.

Health shouldn't be subject to politics. And when we're sick we don't want the opposition voting on it.

The insurance companies are nonpartisan. They pay off like a slot machine either way.

RESISTANCE TO TUBERCULOSIS

Resistance to tuberculosis decreases with age and older animals are relatively susceptible to this infection is the surprising conclusion of Smithburn¹ of the Rockefeller Institute, from his study of experimental tuberculosis in guinea pigs.

Statistical and experimental evidence led earlier immunologists to the generalization that resistance to all infectious diseases increases with age, reaching its maximum in early adult life. After the thirty-fifth year a gradual decrease in antimicrobial defense was postulated.

Some doubt as to the universality of this law may arise from study of the relative susceptibilities of young and adult rabbits to streptococcus and staphylococcus filtrates. Up to the age of 4 months newborn rabbits can be injected intravenously with presumably multi-lethal doses of staphylococcus toxin without appreciable toxic symptoms.² Adult rabbits are killed within twenty-four hours by a fraction of the same dose per unit of body weight. This youthful tolerance to staphylo toxin is not serologically transferable and is conceivably due to the greater "growth vigor" of juvenile tissue cells. Other theories, of course, have been proposed. That there is a similar juvenile tolerance to staphylo toxin and streptotoxin in man is shown by the failure of children to react to endermic tests with these toxins,³ most adult skins being highly reactive.

In order to test the relative susceptibility of different age groups to tuberculosis, Smithburn inoculated groups of normal guinea pigs of different sizes with arbitrary doses of highly virulent and moderately virulent human and bovine strains of *Mycobacterium tuberculosis*. The inoculations were made intracerebrally. Each animal was allowed to succumb to the infection, and the mean survival time per group was thus determined. In one series, for example, a group of five elderly guinea pigs (900 Gm., three females, two males), five middle-aged animals (450 Gm.) and five young guinea pigs (150 Gm.) were each inoculated intracerebrally with 0.00001 mg. of a highly virulent human strain of the tubercle bacillus. The mean survival time for the elderly group was 23.8 days, for the middle aged group 27.6 days, and for the juvenile group 35.8 days.

When subjected to statistical analysis, these differences are significant, particularly when reduced to the basis of dose per unit of body weight. Thus the young animals received on an average 7.7 times the calculated dose per kilogram of body weight given to the oldest group and 3.3 times the middle aged dose. Smithburn concluded from his evidence that resistance to tuber-

culosis "as measured by survival time of guinea pigs after intracerebral inoculation" decreases with age, young animals being approximately ten times more tolerant than elderly controls. Whether or not this juvenile tolerance to tuberculosis occurs in human epidemiology was not discussed.

THE DETERMINATION OF CALCIUM REQUIREMENTS

Henry C. Sherman¹ of Columbia University holds that the American diet is frequently deficient in calcium and that a calcium deficiency may be avoided by regulating the diet to include more foods with ample calcium content. Although the Sherman standards for optimum daily calcium intake are widely accepted, investigators are not agreed as to minimum calcium requirements. One difficulty in determining the basic requirements for such elements as calcium, iron and phosphorus is that they are not accurately indicated by the rate of retention in the body at any given time.

Fairbanks and Mitchell,² who studied factors affecting calcium retention in rats, point out that the highly variable retention of calcium reported in children may be due to the variable condition of their skeletal tissues with respect to calcium storage. This has been emphasized previously, but it appears to be a point that has been overlooked in many discussions of the calcium needs of the body. Boldt, Brahm and Andresen,³ for example, showed that previous depletion of the calcium stores will accelerate its storage.

Fairbanks and Mitchell undertook a study of the rate of retention of calcium during periods of experimental feeding of rats on different calcium intakes. They found that the extent to which the skeleton is saturated with calcium determines the rate of calcium retention, low saturation being associated with subsequent high retention of calcium. Calcium retentions observed under conditions of adequate nutrition are an index of calcium requirements only when the calcium stores have been saturated by appropriate prefeeding. In evaluating experiments in which this precaution has not been taken, more significance can be attached to the lower rates of calcium retention than to the higher as measures of actual requirements. This is in accord with conservatively accepted information concerning the nutritional needs of calcium; namely, that medication with calcium is not indicated unless there is a prolonged dietary deficiency.

The University of Illinois investigators conclude that the actual calcium content of growing rats is dependent

on the calcium content of the diet, if it contains a percentage of calcium inadequate for maximum storage, and on the rate of growth, which is dependent in turn largely on the rate of food consumption. The first relation is a direct one, the latter an inverse one, rapid gains being associated with low calcium content. Furthermore, the commonly accepted belief that females contain higher percentages of calcium in their bodies and in their bones than males of the same age seems to be entirely referable to the slower growth. Finally, since the calcium content of growing rats and the extent of calcification of their bones are dependent on the amount of food consumed as well as on its mineral content, control over the total food intake is essential for accurate interpretation of experimental results.

Current Comment

THE RED TAPE BEGINS TO UNWIND!

If any one is in doubt as to what happens under state medicine, the following example should be convincing: In the case of a woman in the state of New York who was ill, attention was given by a local physician, who then notified the relief official that prolonged medical care would be required. The case supervisor for the public welfare official then sent the following letter:

We are enclosing forms which are to be forwarded to the state department where prolonged medical care is needed.

We are asked to send a letter from the doctor with these forms giving a complete medical history of the patient which will include the date of onset of illness, the diagnostic procedure used and any laboratory findings. *The name, strength and quantity of the material used for injections will be reviewed by a state physician.*

The red tape begins to unwind and before the spool runs out all of medical practice may be wrapped in its meshes.

OXFORD HONORS HARVEY CUSHING

The University of Oxford in July conferred on Dr. Harvey Cushing of New Haven the honorary degree of doctor of science. The event was more than academic, for Dr. Cushing, the *Lancet*¹ says, also received expressions of affection and respect that few other men could command. The famous surgeon was described as a man who had removed more than 2,000 brain tumors, as a great baseball player who had taken up surgery, as an innovator in technic who performed not only with scalpel but with the pen, as the biographer of his friend William Osler, and as a benefactor of the wounded in France in the World War. At a luncheon given by the vice chancellor before the ceremony the guests included Sir Almroth Wright, Sir Richard Livingstone, Dr. E. H. Cushing, a nephew, Drs. Clovis Vincent and Thierry de Martel of Paris, Dr. Arnold Klebs, Professor Bastianelli of Rome, three former surgeons in chief of the Peter Bent Brigham Hospital

in Boston, where Dr. Cushing did much of his surgical work, and former pupils who now hold positions in Brussels, Louvain, Amsterdam, Manchester, Edinburgh, Leeds, London, Oxford and Newcastle-on-Tyne. A distinguished group attended a party also at the Nuffield Institute. On Sunday morning Dr. Cushing gave a clinic demonstrating a case of pituitary basophilism. It was an international occasion. In presenting him for the honorary degree, the orator said:

Ecce chirurgus primarius, qui fausto exitu plus bis millies, ut verbis Ennians utar, tumescens ferro "cere-comminuit brum." Medicis patre, avo, proavo prognatus et in Unversitate Yalensi cum Doctoris gradum tum pilae lusoris litteram adeptus, postquam in Europa quoque disciplinam suam secutus est, domum reversus difficillimam cerebri secundi artem—id quod ipse olim chirurgiae Symplegadas nominavit—aegrotantibus maxime optulair verbis arguebat, factis probavit. Quin ipse in hac arte mirum quantum proventus qui tardius agat melius agere demonstravit. Multum huiusmodi remediis prodesse vim electricam credebat; naturae fortasse medendi facultati diffidebat, nihil certe fortunae permittebat. Idem per viginti annos in Unversitatibus Yalensi et harvardiana Professor quod ipse didicerat, discipulos docuit, quorum complures hodie famam sibi maximam vindicaverunt. Nec scalpello tantum hic usus est sed etiam stilo. Nonne de nervis, de cerebri textura, de glandula pituitaria τέχνην ἔχουσι permulta scripsit? nonne nobis *Idiōtēs* amici sui Willelmi Osler monumentum exegit praeclarissimum? Nunc, cum rude donatus ad nos hospes advenit, ut viro honoribus prius cumulato nos quoque tributum nostrum offeramus, praesento vobis chirurgum eminentissimum, Harvey Cushing, illustrissimi ordinis de Balneo comitem, ut admittatur honoris causa ad gradum Doctoris in scientia.

MAJOR AND MINOR SURGERY

In two recent communications, Hubert A. Royster makes a plea that the term "minor surgery" be eliminated from our nomenclature because of possible implications. He advances the argument that the labeling of certain procedures as minor may mislead an intern or a general practitioner into believing that any condition requiring surgical intervention can be regarded as minor. Only one of 104 surgeons whom he consulted believed the division of surgery into major or minor is justified. The principal objection to the term, it appears, is that it is vague and ill defined. There exist no definite criteria by which to designate any one procedure as minor or major. What appears to be a simple procedure may develop into the most complicated one. What is a minor operation in the hands of a skilful surgeon may prove a major one in the hands of the unskilled surgeon. Such criteria as time required to perform an operation, the mortality, the skill required, the question of anesthesia, the question of whether it can be performed in the office or requires hospitalization are all variables. The suggested substitutes for the term minor surgery, such as office surgery, ambulant surgery or dispensary surgery, are hardly an improvement. Royster argues that all surgery is based on the same fundamental principles and is therefore not divisible. In no other field of medicine does a similar division into major and minor procedures exist. Actually the term minor surgery has largely disappeared from the curriculums of our leading medical schools.

EDITORIAL COMMENT ON THE ARNOLD PRONUNCIAMENTO

THE SOFT IMPEACHMENT

New York Herald Tribune, August 2

The nation is just getting itself adjusted to Mr. Thurman Arnold's novel method of antitrust prosecution by what might be called the soft impeachment. His recent announcement that he was setting out to enjoin the motion picture companies as violators of the law, but was doing so in only the most constructive and friendliest possible spirit, had much to recommend it; here at last, it seemed, was a way through which the antitrust laws might be made into really serviceable instruments of rational industrial regulation. But when Mr. Arnold suddenly extends the same polite constructivity into the nonindustrial problem of group medicine one is not, in the first moment of astonishment, quite so sure.

The implications of the proceeding are so remarkable as rather to overshadow the specific allegations of sabotage against the district medical society. To begin with, Mr. Arnold can scarcely have much confidence that a criminal prosecution would stick in the courts. There are various decisions to the effect that the prohibited restraint of "trade or commerce" must apply to goods or commodities, while the Clayton act specifically excludes the "labor of a human being" as an article of commerce. Surely, a doctor's laborious services could not easily be brought within the scope of the antitrust laws. But the Arnold method is not aimed at a court battle; it proposes rather to extort a consent decree without one.

The consent decree has been used before now to enforce, through the mere threat of prosecution, an extent of governmental regulation which the prosecution itself might fail to sustain. That aspect of Mr. Arnold's sweet reasonableness might not matter so much in the proper field of antitrust law, where there are always plenty of capable opposing counsel; but extended into the problems of medical practice it seems fraught with ominous possibilities.

And there are other peculiar things about this proposal to settle the complex social issues centering around medical care by the kindly intervention of the Department of Justice, with criminal charges and a grand jury investigation. Mr. Arnold himself notes, under the head of "economic results to be expected" that prosecution in the nation's capital will ensure "adequate publicity." (It could ensure little else; for, since medicine, if "commerce" at all, is certainly not interstate commerce, the federal law would operate only in the District of Columbia.) At a moment when the New Deal seems pretty hard put to it for popular issues next year and is clearly working up the health insurance question as a possible means of filling the gap, this device for showering "adequate publicity" upon the matter has an unpleasantly political connotation.

The Department of Justice, for all its excellences, is clearly not the appropriate agency for regulating American medicine. And if its new policy under Mr. Arnold is going to be bent to the uses of political stratagem, it will cease to be an appropriate agency for regulating anything else.

NEW DEAL BUFFOONERY

Troy, N. Y., Times Record, August 2

There is something excruciatingly funny about the antics of New Dealers when somebody challenges their benevolent tyranny. In their own estimation, from the President down, they seem to believe honestly that they are the anointed of the Eternal, infallible in every detail, and therefore entitled to ignore law, courts, custom and all other conventions that civilization erects for its own protection. If the courts are in the way, pack them. If laws oppose a plan, scrap them. If Con-

gress refuses to act on such laws, twist them. If men question New Deal objectives, denounce them.

So the men who are directing the plastic intelligence of the President along radical lines toward collectivism have decided that cooperative medicine, at first voluntary and at last compulsory, must be introduced into the United States while the going is good. The American Medical Association does not approve it. In this attitude it has most of the nation behind it. So the A. M. A. decides to bar from its membership those who favor cooperative medicine—which it certainly has a right to do. Its position is precisely the same as any club which bars this or that group from its privileges; for a club is a voluntary association.

But the New Deal bunch are angry. So the word has gone out that the A. M. A. must be attacked by law. An injunction will be sought compelling it to admit to its membership the New Deal gang of doctors. In short, New Dealism proposes to force its way even into voluntary associations. The next step will be to insist that all newspapers publish all its lying hand-outs and be enjoined wherever they refuse.

There is no law for such compulsory breaking down of social preferences. Censorship cannot go thus far. The New Deal proposal is silly and tyrannous. It has in it not a single ingredient of honest Americanism. It is purely Russian—as are many of the New Dealers. The courts are not yet packed by the Roosevelt régime and there is not a chance that any such processes will win. But that such efforts should be made ought to be evidence enough of the program of repression and dictation which Washington intends to carry out if it can get the power into its hands.

NEW DEAL MEDICAL BLUFF

Indianapolis Star, August 2

The Justice Department apparently is acting under New Deal orders to use threats and coercion on the organized medical profession in an effort to further the schemes of so-called state medicine. The department has accused the medical association of alleged illegal activities against cooperative groups formed to lower the cost of medical care. One of its assistants said a preliminary investigation indicated possible violation of antitrust laws.

An honest difference of opinion exists among members of the medical profession, but nothing to date has justified the attempted interference of government agents, particularly on antitrust claims. Organized medical societies should be able to exercise majority rule in determination of policies deemed necessary for public and professional welfare. Some physicians affiliated with the cooperatives are said to have been excluded from Washington Hospitals. That reported condition in the District of Columbia does not justify blanket charges applying to all the profession.

The government's charges evidently were designed to intimidate the medical profession into acceptance of the socialistic spending contemplated by the New Deal health program. The President's advisory committee recently recommended expenditure of hundreds of millions on a national health program, which would extend governmental paternalism, impose an additional burden on the taxpayers and add to the list of residents who assume with some reason that the government will supply every need for the rest of their lives. State medicine makes almost inevitable a bogging down of professional standards which have contributed to the high plane of scientific progress.

It is true that many cannot pay for medical care. State and local clinics provide aid, much charity work is performed throughout the country and both medical and dental groups are sponsoring time-payment plans. Persons needing professional

attention usually get it, regardless of financial circumstances. The socialistic schemes fostered at Washington, however, are training too many to believe they can become permanent wards of the taxpayers.

A CHARGE OF MONOPOLY

Philadelphia Public Ledger, August 2

Lately there have been several indications that certain federal authorities regard the representatives of organized medicine as enemies. Though admitting the "absence of moral turpitude," the Department of Justice is bringing criminal proceedings against the American Medical Association and the District of Columbia Medical Society, intending to prove that these organizations have violated the antitrust laws by interfering with the workings of a health association of government employees.

The medical groups, it is charged, have threatened expulsion and other disciplines for physicians supplying their services to the Group Health Association, Ltd. It is implied that by doing so they are endeavoring to maintain a monopoly in medicine.

But the long-established rules and policies of organized medicine are mainly designed to defend its standards and codes of ethics. The medical profession is self-governing. And this, perhaps, is what the New Deal Administration doesn't like about the medical men. They are rebels against the policy of benevolent regimentation. They believe they can mind their own business better than Washington. By invoking the antitrust laws the government has gone a long way for a weapon against them.

IS THERE A MEDICAL TRUST?

Philadelphia Record, August 2

The government is starting antitrust action against the American Medical Association, just as if it were a widget manufacturing corporation.

Treating the A. M. A. as if it were just another business will probably offend some of the nation's eminent and distinguished doctors.

But they have brought it on themselves.

Medicine is not a business. It is a science and an art, a great calling set apart from the humdrum round of ordinary activities. But the conservative A. M. A. leadership has been doing its best to act like the board of directors of a watch-fob trust intent on controlling the market.

They have fought "competition" as bitterly as any tight little trade organization. Not the competition of quacks and charlatans (in fighting them the A. M. A. has done brilliant and useful work), but the competition of regularly licensed physicians who have endeavored to work out practical methods of group medical care.

The Department of Justice is proceeding in the case of the Group Health Association of Washington. This is an organization formed by 2,500 government employees who sought to protect themselves against the disastrous expense of major illnesses by combining, hiring doctors, setting up a clinic and meeting expenses by small monthly premiums.

Insurance, no more, no less.

The answer of organized medicine has been the bitterest hostility. Hostility based not on any quarrel with the methods of treatment or the qualifications of the doctors, but on the methods of payment alone—hostility based on the fear of competition.

Doctors working for the group have been threatened with expulsion from the local medical societies affiliated with the A. M. A. One doctor has been expelled. The facilities of hospitals (even in emergency cases) have been denied to doctors connected with the group plan. Every effort has been made to hurl these doctors into the outer darkness.

The Department of Justice, through Assistant United States Attorney Thurman Arnold, has started an investigation. It offers to drop it if the A. M. A. and the local medical society accept a consent decree. Arnold carefully points out that he is not defending group practice but merely trying to "prevent artificial impediments by organized groups" against any legal

efforts to lower the appalling costs of medical care—costs completely beyond the reach of the average worker.

We think this investigation is vital. We think the A. M. A., instead of doing a scientific job of studying group medical practice on its own, has blindly chosen to isolate itself from the major currents of contemporary medical thought. It has disheartened many physicians, as witness the growing rebellions against the A. M. A. leadership in the A. M. A.'s own ranks.

Despite the A. M. A.'s opposition, the drive for health insurance and group practice continues. The Committee of 430, the rebel group in the A. M. A., includes some of the most famous names in medicine. Entire state organizations, such as the California Medical Association, have revolted and plumped for health insurance. On the West Coast the famous Ross-Loos Clinic, offering complete medical care for \$2 per month per family, now has 50,000 members, fifty-five doctors, a five story building, an ambulance fleet.

We hope the A. M. A. comes to its senses. It should be the leader in improving the economics of medicine as it has been the leader in furthering the science of medicine. It has a splendid opportunity. If it is wise, it can retain a position of control as the years bring their inevitable changes.

If it is short sighted, it, and medicine and the public, will be the losers in the end. We don't suggest that the A. M. A. indorse group practice. We urge only that it permit, without hindrance, those experiments which alone can settle the question.

APPLICATION OF THE ANTITRUST LAW TO REGULATION OF MEDICAL PRACTICE

Arizona Republic, August 2

What is this sacred thing, the Group Health Association, that it may not be flouted with impunity? Is it not a long step in the direction of complete regimentation which now seems to have been the aim of the brain trust at the beginning six years ago and, perhaps, would now be well under way but for the intervention of the Supreme Court against NRA? But in many and devious ways that objective is still being approached.

If a membership list of the Group Health Association were obtainable, we think we would find it was largely made up of adherents of the New Deal.

Steps in the name of the Group Health Association have already been put under way against the American Medical Association and the District of Columbia Medical Society as violators of the federal antitrust law. Perhaps if it could be shown that these organizations had encouraged their members to agree upon the fees to be charged by the profession, and that as a result of such encouragement uniform and exorbitant fees prevailed, an action for violation of the Sherman antitrust act might lie.

But as we understand that is not the gravamen. Then what have the intended defendants done to call down upon them the wrath of the New Deal? They have been guilty of the sacrilegious act of speaking disrespectfully of the Group Health Association. They have signified that they want nothing of this association. They counsel the dissociation of their members from the group health physicians in the matter of consultation and hospitalization and other relations which are more or less private and personal. In short, they regard the health group idea as a form of heresy which should not be encouraged. That is, the head and front of the offending of the American Medical Association, a revolt against the New Deal.

The proposed action against the American Medical Association and the District of Columbia Society is quite similar to the proceedings of the National Labor Relations Board, whose interpretations of the Wagner Act are held to be sacred and not subject to questioning. It has thus become a crime to think evil of the rulings of the board.

It is the professed aim of the health group to provide medical and surgical aid for all who are in need of it. We have been making a gradual approach to that aim for many years, but the health group wants it done now, instant. It is in that respect similar to nearly all New Deal projects, lacking in practicality.

We may suspect that the health group is more solicitous for the well-being of a class of physicians who for one reason or

another have fallen short of professional success, than they are that none should be deprived of medical care. For this they would regiment the practice of medicine and establish it on a lower level than that to which it has been brought mainly through the efforts of the men who are now more vigorously opposing regimentation.

If it should happen as a result the action threatened by the department of justice that the practice of medicine should be shorn of its independence and freedom and all practitioners should be reduced as nearly as possible to a common level, it would be a sad day for the country. In their wildest dreams the most insane of radical socialists nearly fifty years ago when the Sherman law was enacted could not have supposed that it could ever be applied to such a scheme for regimentation.

They might, and no doubt did, have in mind complete socialization, but they could not have imagined that it would ever be reached through an antitrust law. Certainly congress never contemplated such a use of the Sherman act.

A NEW USE FOR ANTITRUST LAWS

Philadelphia Inquirer, August 2

Public interest in the antitrust suit which the Department of Justice is now bringing against the District of Columbia Medical Society and the American Medical Association will not be confined to Washington. The widespread adoption of plans for group hospitalization and medical care will focus national attention on this unprecedented action.

Thurman W. Arnold, Assistant Attorney General, charges the organizations of physicians with violating the antitrust laws in attempting to prevent the functioning of a local group health association composed of government employees. Specifically the medical societies are accused of threatening expulsion of their own members who accept employment from the health group and also their removal from staffs of affiliated hospitals.

This alleged procedure is termed by Mr. Arnold an illegal boycott of health group doctors. He charges that the associations are endeavoring to set up a virtual monopoly of the community's medical services.

In proceeding against professional nonprofit organizations, which are not concerned with prices or commodities and in the ordinary sense are incapable of operating in restraint of trade, the Department of Justice has entered a field commonly regarded as outside the scope of antitrust laws.

The Washington plan that has encountered opposition from medical societies differs from the group hospitalization plan recently adopted for Philadelphia with the cordial cooperation of organized medicine. In Washington a group has retained its own staff of physicians and operates its own clinic. Under the Philadelphia plan subscribers take out insurance against the cost of hospital accommodations and treatment.

Whatever the outcome in Washington, Philadelphia has reason to congratulate itself on the agreement recently concluded between the Associated Hospital Service and the County Medical Society that will mean so much to the health of this community.

A MEDICAL CONTROVERSY

Boston Post, August 2

The action of the Department of Justice in charging the American Medical Association with monopolistic practices in connection with the Washington Group Health Association is, indeed, a radical departure from accustomed procedure.

The Group Health Association is a mutual organization of government employees. It provides all medical care necessary for its members by payment of a small membership fee.

Doctors are hired by the year. They earn their complete living in this way. As far as can be ascertained, the plan is working very well for doctors and patients.

Now it is alleged that the A. M. A. and its affiliate, the District of Columbia Medical Society, is attempting to prevent the success of the association by using the following methods:

The first is threatening expulsion of doctors from the A. M. A. for working for the association. The second is

threatening expulsion from the society of doctors who consult with the association. The third is threatening expulsion from Washington Hospitals of the association staff doctors.

It can be seen that the methods charged are underhanded, and, if proven, monopolistic indeed.

There is no question that there is a large element in the medical profession which opposes departure from the time-honored individualistic conception of medical practice. And also there is no question that, in this day of government interference in every walk of life, a socially minded government wants to put over a sweeping plan of nationalistic medicine, as it has put over farm plans, soil plans, flood plans, unemployment plans and electric power plans.

But before we make up our minds that the present action has dragged a raw situation into the light, in which the American Medical Association is attempting to hold up the public for high fees, it is well to scan the record.

The association for a number of years has protected the public against the quacks which sprout like fungi in the broad field of medicine.

There is no subject that the general public knows less about than bodily health.

Illegal practitioners have been winnowed down to a minimum; medical schools of the racket variety have been put out of business; standards of state medical examinations have been raised and fake cures and hospitals have been exposed.

The general standard of medicine is higher in this country than anywhere else on earth. And it has been the voluntary membership of the American Medical Association, a free and unsupervised society, which has done it.

Of course, there has been much complaint against the mandatory methods of the Association, exercised against individuals and in legislative halls. But the ultimate result of it all has been beneficial.

Consequently, the government's present move should not be prejudged until the facts are known.

CLUB FOR MEDICAL 'TRADE'

Philadelphia Evening Bulletin, August 2

Anticipation that there would be something novel and spectacular in antitrust enforcement under Assistant Attorney General Thurman Arnold has been borne out. The proceedings just initiated against the American Medical Association and the District of Columbia Medical Society, intended to lead up to a Grand Jury investigation of the opposition to group medicine from the antitrust point of view, is a coup almost deserving the overworked adjective sensational.

The allegations charge an illegal boycott carried out through threats of exclusion from the District Medical Society, and the actual exclusion from Washington hospitals of physicians on the staff of the Group Health Association, Inc., an organization of government employees to provide themselves with prepaid medical care.

The Sherman Act and other antitrust legislation were expressly stated to be intended to prevent combinations in restraint of trade and commerce among the several states or with foreign nations. The "trust" aimed at was nothing vague or indefinite in the minds of those who pushed this legislation. The popular idea was well embodied in a noted cartoonist's conception of a puffy, bloated plutocrat in dollar-mark checked attire. There was accordingly considerable indignation when in the famous Danbury hatters case the Sherman Act was applied to a labor boycott. The Clayton Act of 1914 made the declaration that "the labor of a human being is not a commodity or article of commerce," and exempted from the operation of the antitrust statutes nonprofit labor and agricultural organizations not having capital stock.

Logically, professional skill and attainments would seem to be equally out of the class of commodities with which the antitrust statutes concern themselves. Of course, as there is no specific exemption in their case, it may be found that the law against restraint of trade applies to the practice of the medical profession. Mr. Arnold contends the law applies to "services" as well as goods.

The Arnold move will probably be widely popular with those who believe that opposition to group medicine and group hospitalization is short sighted on the part of the medical profession, and that if the war on group medicine in the District went to the length charged by the Attorney General the bounds of legitimate self defense were exceeded. But the fairness of the use of this particular club is open to question, especially as long as there are awaiting attention so many charges of violation of the antitrust laws by combinations they were supposedly intended primarily to cover. Such prosecutions would be more prosaic, but they come closer to the intent of the law as commonly understood.

MEDICAL MONOPOLY

Indianapolis News, August 2

An amazing interpretation of the federal antitrust laws is implied in the announcement of the United States department of justice that it is preparing to bring suits against the American Medical Association and other medical societies for violation of the antitrust laws. Coming so soon after the national health conference at Washington, at which differences of opinion between the American Medical Association and the federal administration were expressed, the inference is that the administration has resorted to the antitrust law suit device to bring pressure to bear upon the organized medical profession for approval of the administration public health plan. An assistant attorney general said in a statement accompanying announcement of the suits that the department would consider a consent decree in event that the defendants in the suits decide upon voluntary cooperation. This means, in effect, that the department will not prosecute if the defendants say that they will desist from alleged violation of the antitrust law.

The attorney general's office alleges, in the suit singled out for a test, that the American Medical Association and the Medical Society of the District of Columbia have attempted to prevent the functioning of the Group Health Association, Inc., of the District of Columbia. This is an organization of about 2,500 government employees. It collects dues from the members and, in return, provides them with medical attention and hospital services. The department of justice alleges that the Medical Society of the District of Columbia has sought to dissuade its members from taking employment by this organization, that doctors who have taken this employment have found themselves barred from the staffs of Washington hospitals and that their professional liberty has been restricted by what the department of justice calls "organized medicine."

The medical profession has resisted such organizations as that named in the Washington complaint on the ground that they will result in inferior standards of medical service and will encourage the subservience of the medical profession to lay control under conditions which are strongly dominated by financial considerations. Some of these organizations are alleged to be formed primarily for the financial gain of the promoters. The department of justice does not seem to realize that in attacking medical societies as alleged monopolies it may be clearing the way for a monopoly of unusual danger because of its lay control. The case will be followed with interest because of its deep concern to the health of every one.

THE MEDICAL PROBE

Washington Evening Star, August 2

The Department of Justice, in announcing its proposal to initiate grand jury proceedings against the American Medical Association and the District of Columbia Medical Society, is relying on the assumption that the Sherman Act applies to a monopoly of professional services as well as a monopoly of goods.

That is a novel proposition and a judicial determination of its validity should be welcomed by the medical profession as well as by the courts. The extent to which government can or should regulate the professional work of doctors is a highly debatable proposition, and the first step in resolving it is the ascertainment of how far, as a matter of law, the government can go in that direction.

If the courts uphold the right of regulation it will then be incumbent on the Department of Justice to prove that the members of the medical organizations have in fact combined to do the allegedly illegal acts. Until that proof is forthcoming the public should endeavor to keep an open mind on the question and not become prejudiced against a profession on the strength of charges yet to be substantiated.

The department has suggested that it would recommend withdrawal of the grand jury action if the doctors would agree to sign a suitable consent decree eliminating the allegedly illegal practices. That is a proper attitude for the government to take, provided the grand jury proceedings are in no sense used as a "club" to compel the signing of such a decree.

While it is not likely that the officials of the medical societies will look with favor on the signing of a decree, they should be free to decide that point without being subjected to pressure or promises. The issues here at stake are too important to permit the development of a situation like that in Milwaukee recently, when a federal judge dismissed a grand jury after it had voted Sherman Act indictments against some automobile finance companies because he thought the Justice Department officials had used the grand jury as a device to force acceptance of a consent decree.

MEDICINE AT CROSSROADS

Boston Herald, August 2

The whole question of assuring the American people of adequate medical care, which was discussed at length at the recent Washington conference, has suddenly been focused on one point by the action of Asst. Atty.-Gen. Thurman Arnold in formally accusing the American Medical Association and the District of Columbia Medical Society of violating the federal antitrust laws. It is safe to predict that the settlement of the case will probably influence the methods of the practice of medicine in the United States for years to come.

The facts, at least as Mr. Arnold presents them, are simple. The Group Health Association, Inc., was voluntarily organized a year ago by 2,500 small-salaried government employees to provide themselves with medical care for a small monthly fee. When the association attempted to retain competent physicians, it found that the District of Columbia Medical Society had threatened to expel any of its members who might enter into an agreement with the association. It also discovered that the society had forbidden its specialist members to consult with physicians employed by the association, and that it had prevailed on several Washington hospitals to refuse admittance to the association's doctors. It is well known, as Mr. Arnold says, that the Washington episode is not unique, and that the medical societies have similarly opposed the organization of group medicine association and hospital insurance plans in several other cities.

If these ventures will inevitably lower the quality of medical care and the A. M. A. can demonstrate that certainty, it is on strong ground. Plainly we must not embark on any scheme which will impair existing medical standards. But if the A. M. A.'s objective is merely to freeze our present medical facilities into a state of permanence and to prevent the free and honest trial of new facilities, it is on exceedingly weak ground.

As it has been declared many times in recent years and as it now must be apparent to almost everybody, the very rich and the very poor today receive the best medical treatment. The rich can afford to engage the best physicians and surgeons. The poor can obtain free treatment—often from the same doctors—at a hospital or clinic. But the middle class, the people with incomes of from \$1,000 to \$2,500 a year, usually have great difficulty and frequently suffer real hardships in attempting to meet the cost of a serious illness. The group scheme offers them the opportunity of buying protection against the financial impositions of illness just as most of them now insure themselves against the loss of their homes by fire—through small monthly or yearly payments.

In reply to the antitrust charges, the A. M. A. has immediately revived the bogey of government regimentation and "social-

ized medicine." The essential point is that these voluntary, cooperative organizations—which nobody has to join unless he wants to—really promise to obviate the need of government subsidy and regulation.

Public funds and private charity already take care of the poor sick. Our present objective should be to forestall the necessity of caring for the middle class sick in the same way. Certainly from the taxpayers' standpoint it is much more desirable to encourage 2,500 government employees in Washington—or any other group of citizens—to finance their own medical care through a cooperative arrangement than to deny them that right and invite them to seek public or private assistance whenever they fall ill.

Mr. Arnold was careful to state in his opinion that he is not accusing the members of the medical societies of a moral offense. Indeed, he invited them as "persons of distinction and good will" to cooperate in ending the impasse "so that there may be free and fair competition between the forms of organization and the older types of practice." It is to be hoped that the A. M. A.'s Chicago office will dismount from its high horse and join with the humble laity in a search for the just and intelligent course.

A VERY BROAD INDICTMENT

Washington Post, August 2

In an unusual application of the Sherman Act, the Department of Justice proposes to move against the District Medical Society and the American Medical Association. Assistant Attorney General Thurman Arnold is persuaded that both have acted in monopolistic fashion in opposing the Group Health Association formed here among government employees.

Heretofore the function of the antitrust law has been to break up economic combinations acting in restraint of trade. In invoking it against a representative professional group many confusing considerations enter the picture.

The statement by the Department of Justice "interprets the law as prohibiting combinations which prevent others from competing for services as well as for goods." Under this broad interpretation it might be said that any move of organized medicine to debar quacks is potentially illegal. And it might further be suggested that the entire program of the National Labor Relations Board, founded on recognition of majority labor unions for collective bargaining, is perilously close to violating the Sherman act. An administration which lays great stress on the right of labor to organize should be doubly careful in suggesting that similar action by professional men may be open to legal question.

Despite doubts as to the law in Mr. Arnold's proposal, there is no question of its broad social significance. It will serve to advertise and intensify an issue which concerns intimately every citizen of the land. Possibly it may serve to clarify the main aspects of this issue, though an increase in acrimony seems more likely. The role of the GHA in the case is largely incidental. It represents merely a convenient example of the attempt to improve the economics of health, a movement which organized medicine has thus far done more to oppose than to foster.

Indeed, it seems doubtful whether the GHA can profit in any direct way even if the projected grand jury investigation should sustain the Department of Justice. The local hospitals might be forced to open their doors to the GHA staff. But probably so much antagonism would be cultivated by the court fight that GHA members could have little confidence in using the institutions. It needs only a very casual acquaintance with the medical profession to realize that its leaders are not the type of men who can be coerced into acting against ideals for which many of them make continuous sacrifices. And the intention of the American Medical Association to fight the issue is already abundantly clear.

In view of this situation Mr. Arnold's statement must be regarded as unfortunate, in spite of an obvious effort to assuage the sting in the indictment. And regret at the widening of the breach is strengthened by the recent signs suggesting that organized medicine was on the point of modifying its opposition toward the group health movement. Locally, the GHA president

last week made a very reasonable peace offer to the medical society and, unless reports are greatly mistaken, a disposition to bury the scalpel has been developing among the latter's general membership. On a country-wide scale, the discussions of the National Health Conference summoned here recently are believed to have impressed organized medicine with its obligation to cooperate with rather than to block well meaning attempts to lower the cost of medical care.

Without the best medical leadership any efforts to reach the proper solution of the national health problem is doomed. It is to be hoped that no legal disputations will be allowed to obscure this cardinal fact.

MEDICAL MONOPOLISTS?

Baltimore Sun, August 2

In his statement of his intention to file complaint against the District of Columbia Medical Society on account of alleged efforts to thwart the growth of experiments in group medicine, Assistant Attorney General Thurman Arnold makes it clear that it is his purpose to make possible "free and fair competition between the new forms of organization and the older types of practice." He cites practices which he believes are in violation of the Sherman Act: exclusion from hospitals of doctors who serve members of group health associations and expulsion of such doctors from medical associations. He believes that similar action has been taken by medical societies all over the country, where cooperative groups have appeared.

Whether or not Mr. Arnold can prove his case and make it stand up as applicable under the Sherman law, he has undoubtedly added an interesting chapter to the intense debate on group medicine and state medicine now being carried on in medical circles throughout the United States. The doctors are passionately divided on the subject and in some localities the fighting is doubtless carried on without gloves. Although it is plain from Mr. Arnold's citation of statistics on the relation of health to income that he is friendly to an extension of public medicine, he can hardly be accused of unreasonable action in so far as he is attempting to maintain a competitive situation between the advocates of two forms of medical practice. A hospital is not usually the private property of doctors who hold one view of this question, and it is difficult to understand why doctors who disagree with them on economic matters should on that ground alone be barred from treating their patients in such institutions.

Mr. Arnold's statement and any proceedings that grow out of it ought at least to have the effect of bringing into public discussion the ins and outs of the debate now proceeding among doctors, the possible relation of professional standing and skill to willingness to participate in cooperative schemes for medical care, etc., etc. At any rate, it will be entertaining to observe the medical reaction to the charge that a learned society of professional men has employed practices "in restraint of trade."

SOCIALIZED MEDICINE?

Chicago Daily News, August 2

The announced intention of the Department of Justice to bring suit against the American Medical Association under the antitrust laws raises some interesting questions.

The department, according to the New Deal's new trust buster, Assistant Attorney General Thurman Arnold, thinks that the antitrust laws apply to the offering of services as well as to the production of goods. That, if we are not mistaken, is a new interpretation. The line between offering one's services and offering one's labor is hard to draw. If Mr. Arnold can make this new interpretation stick, will there not be a conflict between the Wagner act, which favors collective bargaining in the offering of labor, and the antitrust laws, which might then be twisted into a weapon against trade unionism?

Specifically, the federal government charges that the American Medical Association is conspiring to make group health plans impossible, by expelling from the association doctors who join in such plans, and by forbidding its members to aid patients

who subscribe to such plans. If it is true that the association does this, and does it in a spirit of opposition, not because it is seeking to maintain high ethical and technical standards in the profession, we think it is following a mistaken course. Mr. Arnold should produce the evidence.

But meanwhile, it is intimated that if the association will change its policy so as to encourage health plans in future, the government may drop its suit. Does this mean that the New Deal, in its continued mood of socialistic experiment, is bent now upon bringing about socialized medicine? If that is the real aim, the administration should say so plainly. Certainly the people are entitled to the best medical care that the science and devotion of the medical profession can provide. But is not the profession already giving such care? Every community has hospital arrangements for patients too poor to pay. Every conscientious physician and surgeon contributes some of his time without charge to the service of the poor, and does so quietly, as a matter of course. But we do not believe that the profession as a whole is in a mood to submit, even under pressure, to New Deal regimentation. And neither do we believe that the average American citizen is in a mood to let the government tell him, when he falls ill, which doctor he must have.

IS THERE A MEDICAL MONOPOLY?

St. Louis Post-Dispatch, August 5

An interesting and perhaps highly significant development in the debate over providing adequate medical care for all the people is the Department of Justice's announcement that it will seek a grand jury investigation in the District of Columbia into the activities of organized medicine. The department was convinced by its own inquiry, says Thurman Arnold, Assistant Attorney-General, that violations of the antitrust laws had occurred.

A workers' health cooperative, similar to many that have sprung up in recent years all over the country, is the center of the dispute. Members of these groups pay dues, in return for which they receive medical care when needed from physicians retained by the organization. Orthodox medical organizations have opposed such groups virtually wherever they have appeared.

In Washington, it is alleged, they attempted to stop operation of the cooperative by threatening its staff physicians, and even doctors who consulted with them, with expulsion from the District Medical Society. Group physicians were barred from practice in Washington hospitals, it is charged. Mr. Arnold views such tactics as "attempts on the part of one group of physicians to prevent qualified doctors from carrying on their calling."

Whether or not actual violations of the antitrust laws occurred, there is no disputing the fact that the actions of organized medicine—the American Medical Association and most of the state and local societies—in opposing various humanitarian health plans have on all too many occasions savored of efforts to safeguard a monopoly for their members.

Millions of persons in this country cannot meet medical bills for their illnesses, not to mention those for periodic examinations on which preventive medicine, the basis of a healthy nation, must depend. On the other hand, there are thousands of physicians who, despite this crying need for their services, are able to make only the barest of livelihoods. To bring demand and supply together is the motive of the plans that have been proposed, which include socialized medicine, compulsory health insurance, government subsidies and voluntary cooperatives.

Of all these, the cooperative is the most moderate, the solution least upsetting to the present system. Yet organized medicine opposes it as well, as was seen a few months ago in St. Louis when the local medical society sought to bring an ouster suit against the Missouri Pacific Hospital Association, which supplies medical services to that railroad's employees. Fortunately, the Attorney-General's office refused to institute the proceeding.

A ferment for better and more widespread health services is stirring among the people, as well as among many forward-looking members of the profession. A committee of 430 members, since grown to more than 1,000, last fall launched a formidable "revolt" to liberalize the attitude of the American Medical Association. The caliber of the men who signed this "medical declaration of independence" proves that the movement must be taken seriously. For instance, among St. Louis physicians on the original list were Vilray P. Blair, David P. Barr, the late Ellis Fischel, Borden S. Veeder, H. L. Alexander, J. Albert Key, Ernest Sachs, Fred Taussig, Evarts A. Graham and Sidney I. Schwab.

Many of the practitioners who oppose a change are undeniably sincere, but their arguments have been refuted in numerous foreign countries where various forms of practice designed to reach the masses at costs within their means are in successful operation, and without the deterioration of ethical standards or medical practices which our own alarmists predict.

A committee of health experts has recently urged an \$850,000,000-a-year program of government public health activities. With such a vast scheme in the air, organized medicine isn't very smart in opposing the moderate cooperative plan, in which no subsidy is paid and no government interference exists. The sole ground for opposition seems to be "unfair competition," but the patient who benefits by a cooperative plan can give that plea little hearing, particularly since under competitive medicine fees are still at a point where an unexpected illness may be ruinous to an ordinary family budget.

The reply of the American Medical Association's president-elect, Dr. Rock Steyster of Milwaukee, indicates no yielding in organized medicine's stand. He insists the A. M. A. "has the right to enforce certain membership requirements and expel members who fail to comply with them," and that "hospitals are private institutions and have the right to determine which doctors shall practice in them."

It is assuredly true that these rights exist, but invoking them against the health cooperatives and their staff physicians betokens a stand against progress, a closed mind against the enlightened experimentation without which medical economics, exactly like medical science, cannot advance.

Mr. Arnold's action may not disclose a "medical trust," but it should cast needed light on the efforts of standpat groups to block a long-needed reform. Punishment of any persons guilty of threats and coercion would be welcome, but better would be the awakening of a cooperative spirit in those who now oppose all changes in the private fee system.

REGULATION GONE MAD

Alton (Ill.) Evening Telegraph

It is announced that the trust busting part of the New Deal is to proceed with criminal action against representatives of the American Medical Association because that body is enforcing its rules against doctors, and in the control of hospitals recognized by the A. M. A. The announcement certainly caused a great surprise to the doctors who have regarded it as their own right to set up such rules and regulations as they deem best for the interests of their profession. The surprise over the announced criminal prosecution of the doctors was not limited to medical men but extended to practically all others. The question is, where can one expect the prosecution to be stopped? Will it take in representatives of all the voluntary associations of cults and crafts and professions which set up rules by which exclusion becomes the penalty for failure of a member to live up to them?

It is recalled that some time ago a suit came to a conclusion in which oil men were penalized for living up to rules and regulations designed for conservation of the oil business, promulgated by them at the very suggestion of a department of the federal government. There are other prosecutions in sight so that people who belong to trade organizations, or to any other groups, have come to be a bit shaky. Is there any reason why, if it is unlawful for such groups as the doctors to organize and make their rules, that it is not unlawful for organized labor to prescribe rules under which its services may be sold and fix

what working agreements will be acceptable? The pattern of the rules of the doctors and of the labor organizations is very much the same. Also, the rules of the associations of special groups generally are very much alike in their working and their objects.

It does seem that the use of criminal prosecution is a poor way for the New Deal to persuade groups to accomplish what the New Deal desires. The difference lies in the fact that socialized medicine is strongly opposed by organized medicine, while it is being advocated by the New Deal, to the extent that criminal proceedings will be launched to make it possible.

The doctor has only his services to sell. He has no assets in his profession to leave his family when he becomes disabled or dies. He thinks he should be allowed to control his professional relations in his lifetime. In that last respect he is like every other person who has worked hard and accumulated something he regards as particularly, peculiarly his own by right of achievement. The lawyer with his bar association, the newspaper man with his A. N. P. A., the dentist with his dental society and other such groups are equally culpable with the doctor, not to mention all the unions in organized labor, all the churches and other religious groups—one and all are just as guilty, just as deserving of prosecution as the doctors, in so far as they may regulate the professions, limiting the actions, the relations of their members to the public and with each other.

The prosecution of the doctors is just another illustration of the madness of the course of the New Deal.

MEDICAL CARE PROBLEMS

New Haven (Conn.) Journal Courier, August 3

Probably what everybody needs most in the present state of the discussion of medical facilities for lower income groups is poise and calm. Assistant Attorney General Thurman W. Arnold has announced an intention of examining in a grand jury investigation the resistance which American Medical Association members and groups are said to make against operation of a group medical care plan among government employees in the District of Columbia. This is the most recent crisis in a debate running back now two or three years; much of it centering, indeed, in New Haven and the Yale Medical School.

Mr. Arnold is a believer in the usages of symbolism in government, having written two books to prove it. It is not at all unlikely that the grand jury investigation is intended symbolically to represent the national government's attitude toward the question of medical care. To conclude that the A. M. A. or its members or its affiliates will be found guilty of violation of the antitrust acts is certainly a long exercise in forward speculation. As Mr. Lawrence suggests in his dispatch this morning, Mr. Arnold may run afoul of statutes protecting labor unions; one thinks particularly of cases in which the antitrust acts were in earlier history sought to be brought to bear against labor unions.

But whatever the result of such litigation as the Department of Justice seems to propose, it is extremely unlikely that medical care plans, federal or otherwise, will get far without the cooperation of the doctors. The possession of medical skill, after all, is something of a private monopoly; the government cannot force doctors to serve against their will; and clearly will not wish to do so. This is no problem in the mobilization of wholly interchangeable laborers to man an assembly line in a mass production factory. No plan for medical care can prosper in the United States without the support of the best practitioners.

It is possible some of those practitioners have been narrow in their judgment of the problem. It is practically certain that narrowness has been overemphasized by critics of the organized profession. Nobody doubts that many competent doctors lack remunerative practice and that many individuals and many areas in the United States lack adequate medical care. The problem will not be settled by tub-thumping on either side. It must be settled in a way which will ensure general cooperation from the medical profession. The public may well demand of both sides toward that end an early meeting of the minds.

SOCIALIZED MEDICINE

Dakota Republican, Vermillion, S. D., August 4

The question of socialized medicine keeps showing up in the public prints. It is quite in line with the other experiments in socialization which the present administration is fostering, most of which are pitiful failures. A doctor working as a federal official on a stated salary would spend a few hours a day waiting on his patients, and the rest of the time making complicated reports for another army of clerks in Washington to file away. He would no longer take a personal interest in his clients, or strive unduly to advance himself in his profession. It is true that the present system works many hardships. The public funds take care of the medical needs of the indigent. The wealthy class can afford the luxuries of the best available medical and surgical attention, while to the great mass of people of moderate means a major illness in the family becomes something of a financial tragedy. But there are some things that money cannot buy, nor political chicanery provide. We like to think of the doctors we all know who will eat when they can, and sleep when their patients don't need them; men who will get out of a warm bed on a blizzard night to follow a snowplow for miles to aid some sick or injured person. We have known what the kindly sympathy and thoughtfulness of the doctor can do when there is illness in the family. To say that our doctors are actuated solely by the hope of pecuniary gain is a libel. Such things as that would soon pass away under socialized medicine. Doctors would become mere hired help, putting in their hours, and looking ahead to annual vacations and eventual retirement pay. We want none of it.

AS OLD AS MEDICINE

Binghamton (N. Y.) Press, August 2

Announcement that the Department of Justice is about to initiate antitrust law proceedings against the Medical Society of the District of Columbia and the American Medical Association sounds big and complicated. Big it is, but not complicated at all. It is just the same old business that started way back yonder.

The world was very young then but old enough to know something about the properties of roots and herbs. On the other hand, there was the school that believed in charms and exorcisms, the Shamans who were somewhat political in their viewpoint and who usually held something of a monopoly on the tribal doctoring.

Those boys never got along with the brewers of potions and extracts. In one form or another they have appeared all through the history of medicine. They clustered around the thrones of medieval monarchs and slowed down the development of medicine as a science. When things got hot they had a few heads lopped off; threw some of the struggling medicos of the Middle Ages into the gaol and dungeon. They were able to and did employ the leverage of government on the members of the profession with whose methods they did not agree.

It is unfortunate that coercive action of the type contemplated is being swung as a club over the head of the American Medical Association and its allied groups which have rejected the federal plan of state medicine. An honest division of opinion exists in the medical profession. The chief objection to state medicine which is entertained by thoughtful medical men everywhere is the danger of its control by the laity and the further reasonable belief that politics would get into it and break down medical ethics and medical standards.

In either or both instances the patient would suffer much more than the doctor.

There is room for plenty of argument on both sides, and both sides are recruited from vast numbers of medical men who are entirely honest in their convictions. They aren't being arbitrary about it. Even a great many of those who oppose the idea of state medicine because of its possible effect upon the patient, whose interest every doctor is bound to safeguard, cheerfully admit that the profession may have to give up some of its rights along with the business groups of the country.

In almost every state and county medical society the country over such honest division of opinion exists. Each side has its own idea of the proper diagnosis. Neither side has, up to now, thought the problem through fully to a point of reasonable solution.

But if coercive methods are employed by the federal government to drive the medical profession of the United States into submission a great many unpleasant things are likely to happen. Even those medicos who are inclined to go along with the administration's plan will resent being driven. There isn't anything in the world quite so stubborn as a doctor. He has to be that way because his battle is with the most stubborn adversary of all.

So the decision to invoke antitrust laws against the medical profession with such obvious purpose is indeed unfortunate. It is to be hoped that the federal government will reconsider before the thing goes too far.

NOW IT'S THE DOCTORS

Wilkes-Barre Record, August 2

It was only a question of time. First the bar got it from the Roosevelt administration. The press got it and is still getting it. The clergymen were dropped like hot potatoes after they had been circularized with questionnaires on the New Deal and had answered according to their own liking but not according to the liking of the administration. Now it is the doctors who are being taken up to the public whipping post. Politely and with some apologies, it is true, but to be spanked, just the same.

American Medical Association has violated the antitrust laws, so charges the New Deal's justice department. A grand jury indictment is to be sought against the medical society of the District of Columbia and the American Medical Association on the allegation that they have expelled a member who cooperated with members of the staff of the Group Health Association, an organization of government employees formed for treatment of its subscribers. Generally the department holds that the District Medical Society, the American Medical Association and some of the officials of both of these organizations "are attempting to prevent this association from functioning."

It seems that the doctors may not have a union. When they combine, the department, in its own words, "interprets the antitrust law as prohibiting combinations which prevent others from competing for services as well as goods."

An assistant attorney general, possibly thinking that among the doctors were some New Deal voters, carefully explained that the department does not take the view that the offenses committed are crimes which reflect upon the character or standing of the persons who may be involved. He specifically declared there was an absence of moral turpitude. But the law is the law and must be obeyed.

Various polls have revealed that professional classes as a whole have had no enthusiasm for the New Deal. The accused doctors who are told in advance that their offenses are not "crimes which reflect upon the character or high standing of the persons who may be involved" should be grateful for this testimony to their character. The bar and the press have had to get along with less tender treatment.

MEDICAL 'UNIONISM'

South Bend Tribune, August 3

In some respects, as the *Chicago Tribune* points out, the medical associations resemble trades unions. They pass judgment on the personal and technical qualifications of persons in the medical profession, extend or withhold the association membership privilege on the basis of that judgment and strive to make nonmembership a serious professional handicap. The *Chicago newspaper's* observation that "there is no union scale for doctors" should be modified. The fees for services are fairly uniform in various communities, with appreciation of local conditions.

It is true, however, that "there are no union hours" for medical practitioners. No medical association has decreed a forty-four hour week for its members. The public, now that

the issue has been intensified by political intervention, should weigh the fact that "the ablest medical men in every community give their services without pay to the poor as a matter of course." Many proponents of socialized medicine argue that the middle class, between the indigent poor and the financially well-to-do, suffers by the present individualistic medical system. The cooperative medical service group in Washington, D. C., on whose behalf the department of justice is intervening for a test case, consists of moderate salaried government employees and of physicians willing to incur medical association displeasure.

Members of the group, pledged to pay \$2 to \$3 a month for medical service whether or not the eventual service actually matches the financial outlay, obviously classify the individualistic system as a liability. Who is to blame? "Few doctors are rich," the *Chicago Tribune* comments, "and many an able physician earns little more than a bare livelihood." Official statistics confirm that. It is pertinent that physicians with distressingly small incomes—some actually have been on the dole in the larger American cities—devoted years and expended much money, meanwhile sacrificing opportunities to earn, for education for that profession.

The *Chicago Tribune* directs attention to the fact that no labor union has been prosecuted by this federal administration for repressive tactics more violent than those attributed to the American Medical association and its District of Columbia subsidiary. "Indeed," that newspaper recalls, "the labor board has repeatedly ordered the reemployment of . . . men guilty of rioting." When the ethical objectives of the American Medical association are given proper consideration it becomes plain that the federal government should be cautious in the impending proceedings. The welfare of the medical profession and the dependent public should have precedence. A "medical trust" investigation with the familiar flamboyant political trimmings designed to break down professional public resistance to the socialized medicine movement, already concrete in legislative proposals, might cause irreparable damage to public health over the long term.

PUTTING THE SCREWS POLITELY ON THE DOCTORS

New York Sun, August 1

The New Deal's Department of Justice has moved against the American Medical Association as a violator of the antitrust laws. Its offense, in brief, is that it has expelled one of its members who cooperated with members of the staff of the Group Health Association, an organization of government employees formed for treatment of its subscribers. It is also alleged that Washington hospitals have been shut against the doctors of the group.

A reading of the opinion of the department would be proof that Attorney General Cummings did not write it. Instead of his trustbusting style it has the soft, even pussy-foot, approach of his assistant, Thurman Arnold. Professor Arnold, while under orders to shake a club at the medical association, possibly remembered that some of its members, when they could reach the polls without neglecting the critical case of Mrs. Jones, voted for the New Deal. So he takes pains to explain that the offenses committed are not "crimes which reflect upon the character or high standing of the persons who may be involved." They have no more moral turpitude than a reckless driver who is a person of "distinction and good will in a hurry to meet his legitimate engagements." However, the Professor explains, the law says so and so and the Department of Justice must follow up.

The accused doctors may keep their silk hats on. They may also reflect that labor unions and farmers may combine but physicians must not do that. They may remember, too, that there is a strong current in the New Deal toward socialism, including socialized medicine. Professor Arnold's lecture on the high cost of medical treatment should amuse at least one veteran practitioner of this town who had 130 calls in a recent month and collected a total of \$3 for his pains.

But the Washington doctors may as well prepare to be indicted. Their lawyers can read to the jury some of Arnold's touching assurances of their lack of moral turpitude.

NATIONAL HEALTH CONFERENCE AND ITS SUGGESTED PROGRAM

J. N. BAKER, M.D.

State Health Officer, Department of Public Health, State of Alabama
MONTGOMERY, ALA.

Whether one is inclined to agree not at all, in part or in toto with the report of the Technical Committee on Medical Care of the Interdepartmental Committee to Coordinate Health and Welfare Activities recently submitted at the National Health Conference held in Washington, every thinking physician, because of its import and tremendous scope, should carefully study its entire content. Specifically, this committee makes five recommendations for coping with existing deficiencies believed to be existent in the Nation's health services:

Recommendation I calls for a pronounced expansion of activities in the fields of general public health, maternity and infancy health services, with particular emphasis on the ubiquitous enemies of mankind, such as tuberculosis, the venereal diseases, pneumonia, cancer and mental disorders. Such pretentious expansions, on a nation wide scale, will call for an additional annual expenditure by federal, state and local governments of some \$365,000,000, and it is recommended that the federal government carry one-half the burden of this proposed expansion. In this recommendation one sees not only recognition but approval given to the principle of federal subsidies to states in perfecting and strengthening local health agencies in their efforts toward controlling and conquering diseases with which they, single handed, are unable to cope. This principle of federal cooperation with states in the health field is already smoothly and efficiently functioning, through the provisions of the Social Security Act with the United States Public Health Service and the Children's Bureau. The need on the part of states—at least most states—for such federal aid has been amply demonstrated during the short time in which the act has been operative. Thus far in the experiences and relationships of state health departments with the federal agencies dispensing the health provisions of this act, there has been little or no tendency to usurpation of the rights and prerogatives which should properly reside within states; in short, the cooperative, not the coercive, spirit has prevailed. In the more recent federal legislation, passed by the last Congress for the purpose of aiding states in stamping out a specific human scourge—the venereal diseases—one sees preserved these principles of cooperation both in the act itself and in the formulated policies of administration. It would seem, therefore, that through this approach of further broadening an already established policy of cooperation between existing federal and state agencies, working in unison and harmony, lasting good should be accomplished through intensified programs specifically aimed at such major and widely distributed problems as the venereal diseases, tuberculosis, malaria, cancer, the pneumonias and the like. As to the importance of the public health significance of these and other health problems, both public health workers and the medical profession are in accord. Should governmental agencies—federal and state—move toward making much larger sums available for these

purposes, it is felt that the details of the machinery for satisfactory operation could readily be worked out between the medical profession and the official health agencies already existing and whose responsibility it now is to administer appropriations made for the protection of the public health. In truth, such is already the practice in many states.

Recommendation II calls for expansion of existing hospital facilities, which, in the committee's opinion, are ill adapted to the varying needs of people living under different social, economic and geographic circumstances. Here one sees a new venture by the federal government into a hitherto unexplored field and is prompted by an apparent utter inadequacy of hospital facilities, at many points and over wide rural stretches, to give hospital care for the necessitous and medically necessitous. This particular problem—either for general hospital facilities or for tuberculous or mental cases—is not an acute one in the larger urban centers or in the more affluent states for the reason that such governmental agencies, possibly more forward looking and progressive, have been able to finance these demands made by society. However, many states, one of which is my own, have not, largely because of financial impoverishment, moved thus far along. No doubt exists in my mind as to the urgency of this need, not only in his own state but also in many other states similarly circumstanced. Nothing approaching adequacy in the realm of hospitalization for the indigent or tuberculous case exists. One is reminded of Tantalus of Greek mythology fame, who, standing neck-deep in water and with luscious fruits dangling overhead, yet suffered death from starvation and thirst because of these vital things ever receding from his lips. This second recommendation not only takes cognizance of an unhappy state of affairs but proceeds even further by suggesting federal financial cooperation with states in remedying these defects. Should not such federal aid, extended to states and sanely administered by state agencies possessing the professional and technical knowledge necessary in this field, prove a wholesome incentive to them to do their full part in bridging over a yawning gap in contemplated nation wide plans for human betterment?

Recommendations III, IV and V need not here and now be discussed. The committee says: "The Committee does not suggest that it is practicable to put into effect immediately the maximum recommendations."

Might not, therefore, attention be focused on the principles embraced in recommendations I and II, for the administration of which, the machinery, in large part, already exists and in which, up until now, no thought of regimentation has been made manifest? Earnest and cooperative effort put forth by all concerned—not the least of which is the profession of medicine—should shed an abundance of light to guide further our faltering footsteps along a tortuous and difficult path.

MEDICAL ECONOMIC ABSTRACT

CHILD WELFARE SERVICES IN
INDIANA IN 1937

The extent of cooperation of the Indiana State Medical Association and the Indiana State Dental Association in the welfare services, and especially in the care of child health in Indiana, is described in a survey of maternal and child health of the Indiana State Board of Health appearing in the May 1938 issue of the *Journal of the Indiana State Medical Association*. Seven committees of the state medical association have cooperated in carrying out the program. The Committee on

Postgraduate Study has conducted a campaign of medical education throughout the state, and the Bureau of Publicity has arranged for approximately 450 health and dental lectures to the public. The State Dental Association has been responsible for a dental demonstration program, consisting of a complete dental office on wheels, which is stationed in selected areas for different periods and where dental care for all indigent children between the ages of 3 and 10 years is supplied free. The state medical association is conducting a study of the causes of infant and maternal mortality in cooperation with the Bureau of Maternal and Child Health.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Society News.—At a meeting of the Pulaski County Medical Society June 6 Drs. Ellery C. Gay and Merlin J. Kilbury discussed surgical and pathologic topics respectively and Dr. John N. Compton, "Nicotinic Acid in Pellagra." All are from Little Rock.—Dr. Silas C. Fulmer, Little Rock, among others, addressed the Ouachita County Medical Society June 2 on diabetic coma.—A recent meeting of the Pope-Yell County Medical Society was addressed by Drs. John H. Moore, Delaware, and Charles R. Teeter, Pottsville, on diphtheria and sulfanilamide, respectively.—Dr. Elizabeth D. Fletcher discussed "Treatment of Dementia Praecox with Metrazol" before the Lonoke County Medical Society in Benton recently and Dr. Robert H. Foster, "The Insulin Treatment of Dementia Praecox."—The Tri-County Clinical Society was addressed in Prescott May 26 by Drs. Robert R. Kirkpatrick, Texarkana, on earache; Merlin J. Kilbury, Little Rock, some lesions of the cervix and uterus, and Joseph H. Sanderlin, Little Rock, the climacteric.

COLORADO

Gift of Medical Caricatures.—Forty-six caricatures of eminent men in medicine have been given to the library of the Medical Society of the City and County of Denver by Earnest C. Watson, Ph.B., professor of physics, California Institute of Technology, Pasadena. They are from the originals of those published in *Vanity Fair*, duplicates of which are to be found in the Royal College of Surgeons in London. They are said to comprise the only complete set in any library west of Chicago. The caricatures were presented to Dr. Samuel Fosdick Jones, Pasadena, Calif., a member of the medical society, who has been interested in the development of the library.

Licensure from National Board Required.—In view of the increasing difficulties of investigating the standard of medical colleges located outside the United States, its territories and insular possessions, the Colorado State Board of Medical Examiners, at its regular quarterly meeting in Denver, July 5, unanimously adopted the following resolution:

Resolved, That no graduate of a college of medicine located outside of the United States, its territories and insular possessions shall be permitted to take the examinations for medical licensure in this state unless he has first qualified before and become licensed by the National Board of Medical Examiners. He may make application to take the examinations for licensure in this state, provided he, at the time of making such application, files with this board a certificate of ability granted by the Colorado State Board of Examiners in the Basic Sciences. This resolution shall become effective immediately and shall apply to citizens of the United States as well as to citizens of other countries.

CONNECTICUT

State Medical Election.—Dr. Joseph I. Linde, New Haven, was chosen president elect of the Connecticut State Medical Society at its annual meeting in Groton June 1. Dr. Hugh B. Campbell, Norwich, was installed as president and Dr. Creighton Barker, New Haven, was reelected secretary. The next annual session will be held in New Haven in May 1939.

Annual Clinical Congress.—The fourteenth annual clinical congress of the Connecticut State Medical Society will be held in New Haven September 20-22. The speakers will include:

Dr. Grantley W. Taylor, Boston, Management of Regional Lymph Nodes in the Treatment of Carcinoma.
Dr. Nicholson J. Eastman, Baltimore, Pyelitis in Pregnancy.
Dr. Edward D. Churchill, Boston, Surgery in Pulmonary Disease.
Dr. Harry Goldblatt, Cleveland, Experimental Observations on the Pathogenesis and Treatment of Essential Hypertension.
Dr. Henry T. Chickering, New York, The Treatment of Pneumonia.
Dr. Cornelius P. Rhoads, New York, The Role of Vitamins in Health and Disease.
Dr. Samuel T. Orton, New York, Certain Disorders in Speech, Reading and Writing in Children and Some Resulting Behavior Disorders.
Dr. Thomas Duckett Jones, Boston, Rheumatic Fever.
Dr. Zacharias Bercovitz, New York, Diagnosis and Treatment of Ulcerative Colitis.
Dr. John Homans, Boston, Thrombophlebitis.
Dr. Harold G. Wolff, New York, Migraine and Its Treatment.

There will be symposiums, panel discussions, five minute talks and a short course on contraceptive devices. Many Connecticut physicians will be on the program, including members of the staff of Yale University School of Medicine.

DISTRICT OF COLUMBIA

Dr. Christie Receives Gibson Award.—Dr. Arthur C. Christie, formerly president of the Medical Society of the District of Columbia, recently received the second Dr. Frank E. Gibson Award in recognition "of meritorious contributions to medical science." The prize is presented by the Washington Medical and Surgical Society and is named in honor of Dr. Gibson, permanent treasurer of the society. Dr. Christie formerly served as professor of operative surgery and roentgenology at the Army Medical School, Washington, as professor of radiology, George Washington University Medical College, and as professor of clinical radiology, Georgetown University Medical School. He was president of the fifth International Congress of Radiology in Chicago in 1937 and has also held this office with the American Roentgen Ray Society and the American College of Radiology. He was born in Pennsylvania and graduated at the Cleveland College of Physicians and Surgeons in 1904.

FLORIDA

District Meeting.—The second annual meeting of the Northwest Medical District Society was held at the Yacht Club, Panama City, July 14. Dr. William J. Blackshear, Panama City, president of the Bay County Medical Society, gave the address of welcome. The speakers on the scientific program included Drs. Taylor W. Griffin, Quincy, "Black Widow Spider Bite"; Jesse N. McLane, Pensacola, "Chronic Maxillary Sinusitis Associated with Dental Caries"; Courtland D. Whitaker, Marianna, "Thoracotomy in Acute Empyema," and William C. Roberts, Panama City, "Obstetric Oddities Occurring in a Single Patient."

GEORGIA

Personal.—Drs. Noel M. Akers, Macon, and Guy V. Rice, Chillicothe, Texas, have been appointed health commissioners of Emanuel and Wayne counties respectively.—Dr. William B. Buckner, Moss Point, Miss., has been appointed health officer of Dougherty County, succeeding Dr. Thomas W. Collier, who resigned Sept. 3, 1937, it is reported.—Rev. William Doris O'Leary, S.J., has been appointed president of Spring Hill College, Mobile; before entrance into the Jesuit order, Father O'Leary was a practicing physician. He graduated from the University of Georgia School of Medicine in 1921.

ILLINOIS

Spotted Fever in Illinois.—The state department of health reports that eleven cases of Rocky Mountain spotted fever have been reported in Illinois so far this year against a total of eighteen cases reported in all previous years. Of the total this year one infection was known to have been imported, four were traced definitely to native tick bites and the remainder are believed to have been caused by native ticks. Four occurred in Johnson County and one each in Clay, Hamilton, Henry, McLean, Marshall, Morgan and Winnebago counties.

Chicago

Dr. Bellows Receives Ophthalmology Medal.—Dr. John Bellows, instructor in ophthalmology, Northwestern University Medical School, has been awarded the medal in ophthalmology of the University of Buffalo for his paper entitled "Biochemical Studies on the Crystalline Lens." The medal is given "for outstanding work in ophthalmology." Dr. Bellows graduated at the University of Illinois College of Medicine in 1930.

Civil Service Examinations.—The Civil Service Commission of the city of Chicago announces the following examinations, among others, on the dates indicated:

Chief sanitary officer, August 23; salary \$6,500.
Chief medical officer, August 30; salary \$6,500.
Bureau chief of communicable diseases, August 31; salary \$5,000.
Medical examiner, September 7; salary \$3,000.
Assistant medical superintendent, September 20; salary \$3,000.

The commission reserves the right under the "subjects, special subject, duties, report of experience, or all of them, to impose oral or practical tests and tests of physical qualifications and health."

INDIANA

Director of Venereal Disease Control.—Dr. Wendall C. Kelly, Princeton, has been appointed state director for venereal disease control, effective July 1. Dr. Kelly has been in charge of a state health center in Princeton for Gibson, Posey, Pike and Warrick counties, where he will be succeeded by Dr. Wallace E. Childs, Madison. He graduated at Indiana University School of Medicine, Indianapolis, in 1936.

KANSAS

Society News.—Dr. Clyde O. Meredith, Emporia, discussed "X-Ray Pelvimetry" before a meeting of the Lyon County Medical Society in Emporia July 5.—The Tri-County Medical Society was addressed in Newton June 6 by Drs. Arthur Graham Asher, Kansas City, Mo., and Galen M. Tice, Kansas City, on "Hypertensive Heart Disease" and "X-Ray of the Gastrointestinal Tract" respectively.

Personal.—Dr. Louie J. Beyer, Lyons, has been appointed a member of the Kansas State Board of Regents for a term of four years.—Drs. Chester E. Joss, Topeka, and James A. Wheeler, Newton, have been appointed members of the Kansas State Board of Medical Registration and Examination for a term of three years each.—Newly appointed members of the Kansas State Board of Health include Drs. Roscoe T. Nichols, Hiawatha, and Bert Anderson, Victoria, and Mr. Howard Rooney, Dodge City, each for a term of three years.

LOUISIANA

District Meetings.—At a meeting of the Fifth District Medical Society in Monroe June 10 the speakers included Drs. Edwin A. Socola on "Banana and Banana Powder Therapy in the Diarrheal Diseases of Infants and Children"; Emmett L. Irwin, the gallbladder, and Thomas B. Sellers, office gynecology.—The Third District Medical Society was addressed June 27, among others, by Drs. Ambrose H. Storck on "Infections of the Foot and Leg" and Roy H. Turner, New Orleans, "Recent Advances in Vitamin Therapy."

Colonel Craig to Retire as Professor of Tropical Medicine.—Col. Charles Franklin Craig, medical corps, U. S. Army, retired, will retire as professor of tropical medicine and head of the department at Tulane University School of Medicine, New Orleans, September 1, and will then be appointed emeritus professor. Born in Danbury, Conn., Colonel Craig graduated at Yale University School of Medicine, New Haven, in 1894, and joined the army medical corps in 1898, becoming colonel in 1918. Among other positions, he was a member of the U. S. Army Board for Study of Tropical Diseases, Manila, from 1906 to 1907; assistant curator, Army Medical Museum, 1909-1913, and curator, 1919-1920; professor of bacteriology, parasitology and preventive medicine and director of laboratories, Army Medical School, 1920-1922; medical inspector of the Hawaiian Department, 1922-1926; commandant and director of clinical pathology and preventive medicine, Army Medical School, 1926-1930, and assistant commandant of the Army Medical Center, 1930 to 1931, when he became professor and head of the department of tropical medicine in Tulane. He was president of the American Society of Tropical Medicine, 1914-1915, American Society of Parasitologists, 1934-1935, and the American Academy of Tropical Medicine in 1935. He is associate editor of the *American Journal of Parasitology* and editor of the *American Journal of Tropical Medicine*.

MAINE

State Medical Election.—Dr. George L. Pratt, Farmington, was chosen president-elect of the Maine Medical Association at its annual meeting in Bar Harbor June 26-28 and Dr. Wilard H. Bunker, Calais, was installed as president. Dr. Frederick R. Carter, Augusta, was reelected secretary.

Society News.—At a recent meeting of the Androscoggin County Medical Society Drs. Roland B. Moore, Portland, and Roscoe L. Mitchell, Augusta, discussed obstetrics.—Dr. Ernest Granville Crabtree, Boston, discussed recognition and management of urologic conditions before the Penobscot County Medical Society in Bangor recently.

MARYLAND

Dr. Katzenelbogen Goes to Washington.—Dr. Solomon Katzenelbogen, associate professor of psychiatry, Johns Hopkins University School of Medicine, Baltimore, has been appointed director of laboratories and research at St. Elizabeths Hospital, Washington, D. C. Dr. Katzenelbogen has also been in charge of the department of internal medicine at the Phipps Psychiatric Clinic. A member of the faculty of Johns Hopkins since 1928, Dr. Katzenelbogen has, among other things, served as head of the laboratory of internal medicine, Medical Faculty, University of Geneva, and chief resident physician of the Hospital Canton, Geneva, Switzerland. He graduated in medicine at the University of Geneva in 1918. His new appointment was effective July 15.

MICHIGAN

State Medical Meeting in Detroit.—The seventy-third annual meeting of the Michigan State Medical Society will be held at the Book-Cadillac Hotel, Detroit, September 19-22, under the presidency of Dr. Henry Cook, Flint. Out of state speakers before section meetings will include:

Dr. Fred W. Rankin, Lexington, Ky., A Combined Operation for Cancer of the Rectum (movie with sound effect).
Dr. Stanley J. Seeger, Milwaukee, Treatment of Burns.
Dr. Kellogg Speed, Chicago, Knee Joint Injuries Exclusive of Fracture.
Dr. Frederick J. Taussig, St. Louis, Lymph Gland Removal in Cervix Cancer: Technic and Results.
Dr. Joseph L. Baer, Chicago, Prolapse of the Uterus.
Dr. Albert D. Ruedemann, Cleveland, Endocrine Disturbances Pertaining to the Eye.
Dr. Oscar V. Batson, Philadelphia, The Surgical Anatomy of the Ear.
Dr. Charles A. Aldrich, Winnetka, Ill., Management of Critical Situations in Childhood Nephritis.

Included among the speakers at the general assemblies will be:

Dr. Frank H. Lahey, Boston, Management of Surgical Conditions of the Common Bile Duct.
Dr. Harold O. Jones, Chicago, Tubal Pregnancy.
Dr. Joseph E. Moore, Baltimore, Syphilitic Primary Optic Atrophy.
Dr. Henry A. Christian, Boston, Certain Cardiorespiratory Correlations.
Dr. Ruedemann, Headaches and Head Pains of Ocular Origin.
Dr. Aldrich, Babies Are Human Beings.
Dr. Taussig, Common Lesions of the Vulva.
Dr. Seeger, Treatment of Burns.
Dr. Batson, Hearing and Deafness.
Dr. Jacob Arnold Barger, Rochester, Minn., Management of the Various Types of Ulcerative Colitis.
Dr. William D. McNally, Chicago, Carbon Monoxide Poisoning.
Dr. Franklin G. Ebaugh, Denver, Obligations of the Medical Profession in Relation to Mental Health.
Dr. Frank E. Adair, New York, Recognition, Diagnosis and Treatment of Breast Cancer.
Dr. John E. Gordon, Boston, Field Studies in Scarlet Fever.
Dr. Henry F. Helmholtz, Rochester, Minn., Application of Recent Advancements in Urinary Antisepsis to Private Practice.
Dr. Russell L. Haden, Cleveland, Clinical Nutritional Deficiency Diseases.
Dr. Speed, Unhappy Results in the Treatment of Fractures.
Katharine F. Lenroot, Washington, D. C., Federal and State Cooperation in Maternal and Child Health Services.
Dr. Robert D. Mussey, Rochester, Thyroid Gland and the Function of Reproduction.
Dr. Roy R. Grinker, Chicago, Newer Methods in Neurologic Diagnosis and Treatment.
Dr. Rankin, Recent Changes in the Teaching and Practice of Medicine.
Dr. Horton R. Casparis, Nashville, The Tuberculosis Program and the Practice of Medicine.
Dr. Allen Fiske Voshell, Baltimore, The Conservative Treatment of Orthopedic Conditions.
Dr. Howard Fox, New York, Treatment of Common Diseases of the Skin.

President's Night will be observed Wednesday evening, when the Andrew P. Biddle Oration will be delivered by Dr. Haven Emerson, New York, on "Public Health the Product of Individual Preventive Medicine." The speakers at the postgraduate convocation Tuesday evening will be Drs. James D. Bruce, Ann Arbor, on "The Challenge of Medical Service" and Morris Fishbein, Chicago, Editor of THE JOURNAL, "Social Aspects of Medical Care." A conference for interns and residents Monday afternoon will be addressed by Drs. Rosco G. Leland, director, Bureau of Medical Economics, American Medical Association, Chicago, on "Value of Medical Organization to the Physician and to the Public"; Louis Fernald Foster, Bay City, "The Place of the Michigan State Medical Society in the Young Physician's Life," and James M. Robb, Detroit, "Pitfalls of the Practice of Medicine—Practical Pointers." A symposium on the business side of medicine will follow this session. Dr. Harrison H. Shoulders, Nashville, Tenn., secretary of the Tennessee State Medical Association, will address the county secretaries' conference Tuesday evening.

MISSOURI

Personal.—Dr. Edwin Lee Miller, Kansas City, received a certificate of merit from the University of Missouri Alumni Association at a luncheon meeting of the Medical Alumni Association, May 3, in Jefferson City. Dr. Miller is the first person from the University of Missouri School of Medicine to receive this award, it was stated.—Dr. Richard B. Schutz, Kansas City, received the cash award presented by the committee on maternal welfare of the state medical society for the most appropriate article appearing in the state medical journal relating to obstetric care. The title of his article was "Bleeding in Pregnancy," published in September 1937. The award was presented at the annual dinner of the committee in Jefferson City May 2.—Dr. Frederick J. Taussig, professor of clinical obstetrics and gynecology, Washington University School of Medicine, St. Louis, has been appointed a member of the state cancer commission, succeeding the late Dr. Ellis

Fischel, chairman. F. T. Hodgdon, Hannibal, a member of the commission, was designated acting chairman, it is reported. —The council of the Missouri State Medical Association held a dinner in Jefferson City May 1 in honor of past presidents of the association. —Dr. Otto H. Schwarz, professor of obstetrics and gynecology, Washington University School of Medicine, St. Louis, was honored at a dinner May 21 in recognition of his twenty-five years as a teacher at the university.

NEW YORK

Society News.—Drs. Arthur J. Bedell and Arthur M. Dickson addressed the Medical Society of the County of Albany June 22 on "Fundus Signs of Constitutional Disease" and "Perforation of Carcinoma of the Stomach" respectively. —At the seventh annual interstate summer meeting of the Medical Society of the County of Chautauqua July 27 the speakers included Drs. Abraham H. Aaron, Buffalo, on "Treatment of Selected Gastrointestinal Conditions from the Viewpoint of the General Practitioner"; Karl A. Menninger, Topeka, Kan., "Contributions of Emotional Factors to Physical Disease," and Frank H. Lahey, Boston, "The Newer Developments in Surgery." —Drs. Alvin R. Carpenter and Charles M. Allaben, Binghamton, addressed the Broome County Medical Society, Binghamton, June 14, on "Fracture of Scaphoid of the Wrist" and "Club Feet" respectively.

New "Long Range" Legislative Health Commission.—The governor has appointed a "legislative commission on a long range health program," consisting of nine legislators and four other members. With an appropriation of \$15,000 to finance its work, the commission has been asked to work out a health program to improve and maintain the health of the people of the state. Following are members of the commission:

Senator Leon A. Fischel, New York, chairman.
Assemblyman Lee B. Mailler, Orange County, vice chairman.
Assemblyman Robert F. Wagner Jr., New York, secretary.
Senator Emmett L. Doyle, Rochester.
Senator Francis L. McElroy, Syracuse.
Senator Joe R. Hanley, Livingston County.
Assemblyman Warren O. Daniels, St. Lawrence County.
Assemblyman Nathaniel M. Minkoff, Bronx.
Assemblyman Meyer Goldberg, New York.
Dr. Thomas P. Farmer, Syracuse, representing physicians.
Mr. R. V. Rickard, New York, representing employers.
Mr. Henry D. O'Connell, Rochester, representing labor.
Miss Elsie M. Bond, New York, representing the general public.

New York City

Medical Exhibits at the World's Fair.—In the news item in *THE JOURNAL*, July 30, page 457, listing the sponsors of medical exhibits at the New York World's Fair in 1939, the name of Ciba Pharmaceutical Products was inadvertently omitted. The Ciba firm is cooperating in development of the exhibit on heart disease and the exhibit on hormones. It was one of the first to assume sponsorship.

Society Sponsors Course in Effective Speaking.—A course in effective speaking, personality training and human relationships will be given by Augustus E. Califano under the auspices of the Medical Society of the County of Queens at the society's building, Forest Hills. An introductory session will be held Friday evening October 7, while the ten subsequent Friday evenings will be given over to the course. Additional information may be obtained from the medical society, 122 Queens Boulevard, Forest Hills.

Changes at Rockefeller Institute.—Appointments and promotions to take effect on or after July 1 were recently announced by the Rockefeller Institute for Medical Research. The following were promoted from associate to associate member:

Rene J. Dubos, Ph.D. Dr. Rafael Lorente de No
Kenneth Goodner, Ph.D. John B. Nelson, Ph.D.

The following were promoted from assistant to associate:

Dr. Albert Claude William C. Price, Ph.D.
Joseph S. Fruton, Ph.D. Dr. Charles V. Seastone Jr.
Dr. John G. Kidd Dr. Joseph E. Smadel
Dr. Colin M. MacLeod Philip R. White, Ph.D.

Max A. Lauffer Jr., Ph.D., was promoted from fellow to assistant. The new appointments include the following assistants:

Dr. Jorge Casals-Ariet Dr. William F. Friedewald
Dr. Smith O. Dexter Jr. Rollin D. Hotchkiss, Ph.D.
Dr. Thomas D. Dublin Dr. Francis H. Wright

Dr. Paul B. Beeson has been appointed resident physician at the hospital and the following have been appointed fellows:

Mr. Mark H. Adams Isabel M. Morgan, Ph.D.
Dr. Konrad Dohrner Ernst Scharrer
Dr. Robert S. Dow

OHIO

Society News.—Dr. Eben L. Brady, Marion, was elected president of the Ohio Public Health Association at the recent annual meeting in Columbus and Dr. Charles A. Doan, Columbus, secretary. —The council of the Academy of Medicine of Cincinnati has approved the organization of a speakers' bureau to provide speakers on medical subjects for lay audiences; the committee on public relations will work out the details.

OREGON

State Medical Meeting at Timberline Lodge.—The sixty-fourth annual session of the Oregon State Medical Society will be held at Mount Hood Timberline Lodge, August 24-27, under the presidency of Dr. Charles T. Sweeney, Medford. The guest speakers will be:

Dr. Cyrus C. Sturgis, Ann Arbor, Mich., Coronary Artery Disease.
Dr. Don C. Sutton, Chicago, Principles of the Treatment of Heart Disease.
Dr. Alfred W. Adson, Rochester, Minn., Surgical Treatment of Hypertension.
Dr. Edward C. Moore, Los Angeles, Carcinoma of the Right Colon.

Among the Oregon physicians participating in the program are:

Dr. Egon V. Ullmann, Portland, The Prevention of Recurrent Herpes.
Dr. William Ronald Frazier, Portland, Treatment of Threatened and Habitual Abortion and Report of Two Cases.
Drs. Fred N. Miller and Marion G. Hayes, Eugene, Streptococcal Pneumonia of Mild Severity.
Dr. Charles D. Donahue, Eugene, Renal Tuberculosis.
Dr. Wilmer C. Smith, Portland, Further Observations on Fractures of the Carpul Navicular.

The guests will conduct round table discussions and Dr. Vernon A. Douglas, Salem, will preside at one for health officers. Entertainment will include the twelfth annual golf tournament, horseback riding and a mountain climb.

PENNSYLVANIA

Society News.—At a meeting of the Franklin County Medical Society in Chambersburg, July 19, Dr. Joseph H. Barach, Pittsburgh, spoke in the afternoon on "Underlying Principles and Treatment of Diabetes" and in the evening "A Medical Tour of South America." —At the annual meeting of the Lehigh Valley Medical Association at Pocono Manor July 21 the guest speaker was Dr. Rosco G. Leland, director of the Bureau of Medical Economics of the American Medical Association, Chicago, on "The National Health Survey and the General Subject of Medical Economics." Dr. Harvey P. Feigley, Quakertown, president of the association, gave his official address on "The Family Physician—His Future."

Philadelphia

Medical Officer Receives Navy Cross.—Lieut. Clark G. Grazier, U. S. Navy, formerly of Philadelphia and now stationed at Cavite, P. I., attached to the U. S. S. *Augusta*, was honored with the Navy Cross June 30 in recognition of his conduct when the gunboat *Panay* was sunk by the Japanese last December. Lieutenant Grazier was the only physician on the boat. In a report to the Secretary of the Navy Lieut. Commander James J. Hughes said that Dr. Grazier "displayed coolness, ability and resourcefulness with his treatment of the many wounded, both while under fire aboard ship and under very difficult conditions ashore." Dr. Grazier was graduated from Jefferson Medical College in 1931.

Pittsburgh

Personal.—Dr. Charles Edward Ziegler, professor of obstetrics, University of Pittsburgh School of Medicine, received the honorary degree of doctor of science at the annual commencement of Dickinson College; he graduated from Dickinson in 1896. —Mr. Harry B. Meller, managing director of the Air Hygiene Foundation of America and for many years in charge of air hygiene research at Mellon Institute, received the honorary degree of doctor of science at the University of Toledo June 13. Mr. Meller is also chief of the bureau of smoke regulation of the department of health.

SOUTH DAKOTA

Society News.—Dr. John Raymond Kleyla, Omaha, addressed the Seventh District Medical Society recently in Sioux Falls on "Recent Advances in the Treatment of Lobar Pneumonia."

Committee on Industrial Health.—A committee on industrial health has been appointed by the council of the South Dakota State Medical Association. According to the secretary of the association, the new appointees were selected on account

of their location in the larger industrial communities of the state. Included on the committee are Drs. Raymond W. Mullen, Sioux Falls; Robert J. Jackson, Rapid City, and Paul P. Ewald, Lead.

TENNESSEE

University News.—Dr. Andrija Stampar, formerly chief medical officer of Yugoslavia, lectured at the Vanderbilt University School of Medicine, Nashville, recently on "Rural Health Activities in China" and "Maternal and Infant Welfare in the Soviet Union."

Society News.—The annual meeting of the Upper Cumberland Medical Society was held at Red Boiling Springs June 7-8. Among the speakers were Drs. William D. Haggard and James A. Kirtley Jr., Nashville, "Studies in Gallbladder Diseases Based on 841 Operations"; Thayer S. Wilson, Gordonsville, "Hypertension and Its Management"; Herman Spitz, Nashville, "Milk Allergy"; Carl C. Howard, Glasgow, Ky., "The Value of Clinical Symptoms," and John T. Moore, Algood, "Sulfanilamide."—Dr. Cassius W. Friberg, Johnson City, addressed the Greene County Medical Society, Greeneville, June 7 on a proposed program for maternal welfare sponsored by the state medical association; Dr. Cecil B. Laughlin, Greeneville, spoke of "The Heart Case as a Surgical and Obstetric Risk."—Dr. Fred H. Albee, New York, addressed the Chattanooga and Hamilton County Medical Society June 9 on "Restoration of Blood Supply in Fractures of the Hip in Bone Graft" and "Restoration of Motion in Bony Stiff Joints."

UTAH

Plague Infection.—According to *Public Health Reports*, plague infection was found in seven fleas collected May 20 from fifteen desert wood rats, *Neotoma desertorum*, shot and trapped from eleven to fourteen miles northwest of Kanab, Kane County.

GENERAL

Society News.—The Central Society for Clinical Research will hold its eleventh annual meeting in Chicago at the Drake Hotel, November 4-5. Dr. Lawrence D. Thompson, 4932 Maryland Avenue, St. Louis, is the secretary.—The Clinical Orthopaedic Society will meet in Nashville October 7 and Birmingham, Ala., October 8. Dr. H. Earle Conwell, Medical Arts Building, Birmingham, is the secretary.

Medical Art Association.—Dr. Alfred Braun, New York, received the grand prize for the best piece of art in the first annual exhibition of the American Physicians' Art Association in San Francisco in June. Dr. Braun's work was an oil entitled "Portrait of an Italian." One hundred and ninety-six exhibitors displayed 559 pieces of art. Dr. Francis H. Redewill, San Francisco, was chosen president of the association at the recent meeting; Drs. Herbert L. Treusch, Atlanta, and Henry N. Moeller, New York, were named vice presidents; Max Thorek, Chicago, secretary, and Raleigh W. Burlingame, San Francisco, treasurer.

Association Does Not Sponsor Promotion of Infant Health.—Word has been received from Portland, Ore., that the Alys May Brown Production Company (no address is given) claims to represent the American Medical Association in conducting a baby health conference in conjunction with the 1938 national encampment of the U. S. Spanish War Veterans to be held at Portland September 11-15. The American Medical Association has no commercial agents for such purposes and disapproves in general such commercial promotions of infant health. For years the Association has been publishing record cards and instructions for the conduct of baby health conferences of a bona fide character. These are available only with the approval of the county medical society in the community where the conference is to be held.

International Pharmacopeial Commission.—At a recent session of the Health Organization of the League of Nations an international commission was appointed to promote uniformity of standards for potent medicines. Dr. Charles H. Hampshire, London, is chairman, and members are Prof. H. Baggesgaard, Copenhagen; Prof. V. E. Zunz, Brussels; Prof. M. Tiffeneau, Paris; Prof. R. Eder, Zurich; Prof. L. Van Itallie, Leyden, and Ernest Fullerton Cook, Pharm.M., Philadelphia. A representative from Russia was also to be appointed. The commission plans to compile a list of the more important medicines used throughout the world and to invite the pharmacopeial commissions in various countries to prepare model monographs, which when finally approved will be presented to

the pharmacopeial commissions of the world in the hope that they may bring about uniformity in titles, definitions, descriptions, tests for identity and purity and methods of assay.

Doctors Wanted for Service in China.—The National Christian Council of China is appealing for six physicians at the earliest moment for war service in China. Six are asked for from the United States, four from Great Britain and two from Canada. Physicians answering the call should be unmarried, in good physical health able to endure the hardships of field service and have special experience in surgery if possible. Passage to and travel in China will be arranged. The remuneration is small, with the minimum term of service to be at least one year. The National Christian Council of China through its commission on medical work in cooperation with the several missions and the International Red Cross Committee will direct the work of physicians. The work will be almost entirely that of war relief. Inquiries should be addressed to Dr. Edward H. Hume, director, Christian Medical Council for Overseas Work, room 1109, 156 Fifth Avenue, New York.

Tennessee Valley Meeting.—Dr. Forrest S. LeTellier, Knoxville, Tenn., was elected president of the Tennessee Valley Postgraduate Medical Assembly at its annual meeting in Knoxville June 22-24. Vice presidents are Drs. Carlisle R. Petty, Lynch, Ky., and James F. Pate, Canton, N. C., and Dr. Jesse C. Hill, Knoxville, was reelected secretary. Among the speakers were:

Dr. Arthur E. Hertzler, Halstead, Kan., Nonsurgical Disease of the Stomach.

Dr. William H. Higgins, Richmond, Va., Medical Aspects of Neoplasms of the Lung.

Dr. Richard Kovacs, New York, Of What Use is Physical Therapy for the Private Practitioner?

Dr. David T. Smith, Durham, N. C., Diagnosis and Treatment of Pellagra with Nicotinic Acid.

Dr. William D. Haggard, Nashville, Manifestations of Gallbladder Disease, with Analysis of 841 Cases.

Dr. Arthur U. Desjardins, Rochester, Minn., Radiotherapy for Inflammatory and Malignant Conditions.

Dr. Edward Julius Stieglitz, Chicago, The Application of Renal Function Studies.

Dr. Francis C. Grant, Philadelphia, Operative Procedures for the Relief of Pain.

Dr. Louis A. Buie, Rochester, Minn., spoke at a banquet on "The Featherless Peacock."

American Board of Plastic Surgery.—Announcement is made of the establishment May 23 of the American Board of Plastic Surgery as a subsidiary of the American Board of Surgery. Officers are Drs. John S. Davis, Baltimore, chairman; George M. Dorrance, vice chairman, Philadelphia; Vilray P. Blair, secretary-treasurer, St. Louis. Members are Drs. James Barrett Brown, St. Louis; Robert H. Ivy, Philadelphia; Harold L. D. Kirkham, Houston, Texas; William S. Kiskadden, Los Angeles; Sumner L. S. Koch, Chicago; William E. Ladd, Boston; Gordon B. New, Rochester, Minn.; George Warren Pierce, San Francisco; Ernest Fulton Risdon, Toronto, Canada; Ferris Smith, Grand Rapids, Mich.; Jerome P. Webster, New York, and John M. Wheeler, New York. The objectives of the board are to issue a certificate of qualification to all those meeting the board's requirements of training in plastic surgery; to conduct examinations for those candidates who meet its requirements and seek its qualifications; to improve and widen the existing opportunities for the training of the plastic surgeon; to study and evaluate local and foreign teaching centers and opportunities for experience in and the study of plastic surgery. The term of membership on the board will be for six years, except in the instance of the original board's membership which shall be for six, four and two years respectively. Two types of certificates will be issued: covering the general surgical field or one or more special fields. Two groups of candidates will be recognized: those to be certified without formal examination as to professional qualification and those to be formally examined. The former will be known as Founders. This group will include those invited by the board to make application and those who, submitting their applications within two years from the date of the beginning of operation of the board, have received the approval of the examination committee, have met the requirements of the Founders group and who, at the time of the board's organization in addition to possessing satisfactory moral character and ethical standing in the profession are generally accepted as technically prepared to do work of satisfactory quality in this field. All candidates eligible for examination must possess the preliminary and basic medical qualifications accepted by the Advisory Board of Medical Specialties of the American Medical Association. The qualifying examination will be divided into Part I, written and Part II, oral and practical. Part I will deal with the theory and practice of plastic surgery in the field in which certification is asked and include questions on

the management of local and general anesthesia, shock, hemorrhage, the handling of tissues and related bacteriology and also surgical accidents. Part II will include the exhibition of patients who have undergone or are undergoing treatment; examination, diagnosis and presentation of a plan of correction by the applicant of cases provided by the examiners; oral examination of the applicant and observations made in the operating and treatment rooms and wards. The fee for Group A (Founders) will be \$25, while the fee for Group B will be \$75, \$25 to be payable on registration; \$25 for Part I and \$25 for Part II. Reexamination may be made as often as desired, provided one year elapses between examinations. The American Board of Plastic Surgery bears the responsibility of deciding who is fitted to do plastic surgery but a veto by the American Board of Surgery on any person will be either accepted by the former or made the occasion of a conference of representatives of the two boards.

CANADA

Canadian Medical Election.—Dr. Frank S. Patch, Montreal, was elected president of the Canadian Medical Association at the annual meeting in Halifax in June and Dr. Kenneth A. MacKenzie, Halifax, was installed as president. The next annual session will be held in Montreal.

British Columbia Meeting.—The forty-sixth annual meeting of the British Columbia Medical Association will be held at the Empress Hotel, Victoria, B. C., September 15-17. Lectures by seven guest speakers will constitute the program, as follows:

- Dr. Hans Lisser, San Francisco: Maxillary Sinusitis; Clinical Observations on the Present Status of the Sex Hormone Therapy; Indications for and Prognosis of the Substance.
- Dr. Edwin G. Bannick, Seattle: Acute Peritonitis; Treatment of Severe Burns.
- Dr. William Boyd, Toronto: Pathology of the Gallbladder; Tumors of the Neck; Bacterial Infection of the Heart.
- Dr. Alton R. Kilgore, San Francisco: Treatment of Peripheral Vascular Diseases Threatening Gangrene; Extra-Abdominal Diseases Simulating the Acute Abdomen; Practical Considerations in the Handling of Acute Appendicitis and Its Complications.
- Dr. Alfred T. Bazin, Montreal: Cancer of the Breast; Cancer of the Colon and Rectum.
- Dr. Kenneth A. MacKenzie, Halifax, N. S.: Treatment of Hypertension.
- Dr. Louis H. Newburgh, Ann Arbor, Mich.: Nature and Management of Nephritic Edema.

LATIN AMERICA

Tuberculosis Campaign in Cuba.—The Cuban government has appropriated a million dollars for a health program in which an intensive campaign against tuberculosis is being developed under the supervision of Dr. Wilson G. Smillie, Dr. Edgar Mayer and Morton C. Kahn, Ph.D., of Cornell University Medical College, New York. Clinics have been established in the state of Havana and in Oriente, staffed by experts in tuberculosis work, and it is planned to extend these clinics into all sections of Cuba. Adults as well as children are undergoing tuberculin tests, the survey being especially aimed at testing school children, food handlers and tobacco workers. Provision is already being made for hospitalization and treatment of those found to have tuberculosis. Renovation of L'Esperanza Hospital, near Havana, has made 800 beds available and another 800 will be furnished in a new hospital under construction in Trinidad, according to the *Bulletin of the National Tuberculosis Association*.

FOREIGN

Building for American Hospital in Turkey.—Construction will soon begin on a new building to house the American Hospital in Istanbul, Turkey, which, according to the *New York Times*, will cost \$200,000 and be of reinforced concrete. It is made possible by contributions from American and other foreign residents in Istanbul, from friends of the hospital in the United States and chiefly from large American oil and tobacco companies with interests in the Near East. Rear Admiral Mark L. Bristol, retired, U. S. high commissioner to Turkey from 1919 to 1927, is president of the board of directors of the hospital in America. The director of the hospital in Istanbul is Dr. Lorrin A. Shepard, an American who was born in Aintab, Turkey, but received his medical training in American schools. The hospital, founded in 1890, has been quartered in a rented building. The new building will be in the Pera section of the city. W. Stuart Thompson, architect, New York, sailed July 16 to organize the work. The staff of physicians and interns is entirely Turkish. The Turkish government is cooperating fully with the institution because it operates a training school for twenty nurses. Under the direction of two American nurses, Turkish girls receive a three year training course and then go to government hospitals.

Annual Meeting of British Medical Association

At the 106th annual meeting of the British Medical Association, which took place at Plymouth, the president, Dr. Colin D. Lindsay, said that the credit of the general practitioner was sinking but that a reaction from that attitude was inevitable. The more the public was educated and the more health services extended into the lives of the people, the more would there be required an active and intelligent family doctor service. It would be no corps of clerks and would require a wide professional training to insure the early recognition of diseases and the proper coordination of specialized services, which were daily becoming more abundant. The amount of functional nervous diseases in the community was very large, and owing to the lack of any obvious disability, except in the later stages, it was only the general practitioner who could lead the attack. Medical psychology might well come into its own. Even now all general practitioners were to some extent psychotherapists. They would be much more effective if their training included some instruction in the principles of medical psychology. All direct contact with the public as individuals should be in the first instance through the family doctor.

At the back of the family doctor service there must be a specialist service. Medicine had grown so much that it was impossible for any one person to be proficient in every branch. However, the tendency to dis sever the various organs of the body went too far. The family doctor was also a specialist, in the recognition of disease in its early stages and in helping in the many ills that beset his fellow men. The intensive search into the origin of cancer pointed to the probability that malignant growths rarely developed suddenly; there was a pre-cancerous stage, usually lasting for years, in which cancer developed from minor ailments which might have been rectified if their significance and possible danger had been recognized. More attention should be paid to minor ailments. It had been estimated that 40 per cent of all illness was due to the patient's own action. If this was true, and he had found it so, a vast amount of sickness could be avoided. This required willingness on the part of the patient to talk over his minor ailments with his physician instead of using self medication assisted by the pharmacist. The general practitioner saw the beginning of disease, the specialist mainly the end. There was no reason why one branch should from its nature be more eminent than the other. They were essentially complementary, and each required attainments of the highest order.

Only through education of the public can credulity in regard to advertised remedies be removed. Because of the superstitious ignorance of the public there had grown up an enormous advertisement literature for remedies claimed to cure not only every known disease but also diseases invented for the purpose of being "cured" by some particular remedy. This trade could flourish only with a public which knew little or nothing. The health of the nation was now much in the public eye, and unless physicians guided the enormous amount of enthusiasm that lay behind the campaign there was danger that it might do more harm than good. They should go further than that. Teaching in elementary biology, anatomy and physiology should be an essential part of all education, however elementary.

THE PROBLEM OF REFUGEE PHYSICIANS

The political persecution in Germany and Austria has created a problem for the free countries, which was discussed at the representative meeting of the association. The number of foreign physicians admitted to the Medical Register in 1937 was

forty; twenty-eight have become members of the association. In 1938 so far the number is twenty-one. A deputation consisting of representatives of the Royal Colleges of Physicians and Surgeons, the Universities of Oxford, Cambridge and London, the British Medical Association and the Society of Apothecaries was received by the home secretary, Sir Samuel Hoare. He said that the position of physicians in Austria was lamentable and that something must be done by civilized nations to meet the emergency. The deputation felt that some gesture of humanity ought to be made by the medical profession and therefore suggested that a strictly limited number of physicians should be received after their claims had been investigated by a special advisory committee. It was also suggested that the senior men might work in laboratories supported by charitable funds and that the younger men before going into practice should be required to undergo specified training and examinations. Apprehension was expressed by some speakers at the representative meeting as to the results of admitting aliens first from one country and then from another. A strong appeal was made by one speaker on the score of humanity that refugees whose prospects had been dashed to the ground through no fault of their own should be given the privilege of going into certain British colonies to practice. The resolution was adopted "That the council be asked to give consideration to the effect on medical practice in the empire of the recent influx into this country of medically qualified aliens, and to report thereon."

RECOGNITION OF CHIROPODISTS

A resolution was moved rescinding one passed by the representative body in 1934 refusing official recognition to chiropodists in a more extended field than corns and callosities. It was pointed out to the representative meeting that the Incorporated Society of Chiropodists gave two years' training and that students were rigorously instructed as to the limits of their practice. They were forbidden to advertise or to use anesthetics and manipulative or operative treatment. The foot clinics were doing good work which could not be done by hospitals unless they had on their staff persons trained as chiropodists. The resolution had already been passed by the council of the British Medical Association by a large majority. They were fully alive to the difficulties; acceptance would mean departure in a small field from the principle that only those with a full medical training were capable of diagnosis. The resolution was opposed on this ground. It was pointed out that a similar claim was made by the sight-testing optician. In the sphere of diagnosis the chiropodist was to be left free, but in therapeutics the sphere was to be limited. On the other hand, it was argued that we should go on needing chiropodists and that this was an ideal opportunity to get control of their practice. The resolution was carried, as also was another requiring chiropodists to confine themselves to chiropody, which was defined as "the treatment of malformed nails and superficial excrescences occurring on the feet, such as corns, warts, callosities and bunions."

CONTRIBUTORY HOSPITAL SCHEMES

It was moved that as the Hospital Saving Association (which collects subscriptions from persons who may require hospital treatment) had hindered the normal development of private practice and that as similar results are likely to follow other contributory schemes the council be asked to review the whole position. The hospitals were much abused. A considerable number of the patients attending could afford to pay the fee of a general practitioner or consultant. On the other hand, it was pointed out that the Hospital Saving Association had advantages: (1) The contributors felt that they were being dealt with otherwise than by charity; (2) the family doctor could send his patient with a note to the hospital without fear that he was abusing the work of the hospital, and (3) every

voucher had on it the British Medical Association limits of income. It was argued that the outpatient departments of the hospitals should be consultative departments only. The motion was carried unanimously.

SYNTHETIC HORMONES

In the section of medicine Sir Walter Langdon-Brown opened a discussion on organotherapy. The cooperation of organic chemists with biologists had led to the preparation of synthetic hormones, and it had been found that simpler chemical substances than those found in nature might be adequate to produce the biologic effect. These basal groups were, in Dodd's happy phrase, "skeleton keys which can pick the physiologic lock." We were still entirely without any conception as to why a particular cell should be sensitive to a particular chemical substance or why the same substance should augment the activity of one type of cell and inhibit that of another. Evans had shown that the response of the dachshund and the sheep dog to injections of the pituitary growth hormone were entirely different. Langdon-Brown expressed the hope that research on the synthetic hormones might effect two things: (1) the discovery of simple basal groups which could produce the biologic effect and yet escape disintegration by the digestive juices and (2) material reduction in the cost of production. At present the cost was prohibitive except for the very rich and for the hospital class.

AIR RAID PRECAUTIONS

Dr. G. C. Anderson, medical secretary, announced that in accordance with the request of the committee of imperial defense and with the help of an emergency officer in every division of the association a register of physicians had been drawn up. It listed 80 per cent of the members of the medical profession who volunteered their services in case of national emergency. The government had asked that the register be kept up to date. In the autumn those who volunteered would be asked whether their intentions still held and whether they would absolve the association from the understanding to keep their reply secret. With permission the authorities could be supplied with the names by area and by age group of those who were willing to volunteer whether for services overseas or for air raid precautions. Mr. McAdam Eccles brought forward a motion asking for the appointment of medical committees on air raid precautions to assist municipal authorities if an emergency arose. In the event of war the younger physicians would be called up for military service, but those over 50 did not know exactly what they would have to do in case of emergency. In view of the information given by the secretary, Mr. Eccles withdrew his motion.

Monument in Memory of World War Physicians

The sanitary corps of the French army includes not only physicians but also dentists, pharmacists, nurses and other hospital aids. June 5 a monument erected at Lyons in memory of members of the corps who were killed or died while in service during the World War was dedicated by the prime minister, Mr. Daladier. A glowing tribute was paid to the work of the corps. Of 22,000 physicians practicing in France in 1914, over 18,000 were mobilized. At the time of the armistice there were 21,181 physicians in the sanitary corps. Ten per cent, or 2,108 of the physicians in service, died as the result of wounds or disease from 1914 to 1918. Of 3,821 pharmacists, 321 died; of 1,000 dentists, 142 died; of 5,238 hospital officials, 500 died; of 120,000 male nurses, 9,213 died, and of female nurses 600 died, 132 after air raids.

End Results of Mediastinal World War Injuries

Two papers read at the meeting June 1 of the Académie de chirurgie of Paris will be of great interest to military surgeons. Prof. René Le Fort of Lille was able recently to follow up fifty-five of ninety-three cases of injury of the heart and mediastinum, which he had observed during the World War. In four of these fifty-five cases operation had not been performed. The foreign bodies which were removed included thirty-two shell fragments, twenty bullets and two hand grenade splinters. In the majority of the cases operation had been done within three months after the injury. In fifty-one the pension received had averaged only 24 per cent of the former earning power, and in those in which missiles had been extracted from the heart (six cases) it had been only 30 per cent. The proportion of excellent end results was 57 per cent for the cases in which operation had been performed and 25 per cent for those in which no extraction took place. Professor Le Fort reported a case in which a mediastinal abscess had developed sixteen years after lodgment of a shell fragment near the root of the right lung. No operation for the removal of the foreign body had been performed at the time of injury. About five days after a recent drainage of the abscess and removal of the shell fragment the patient had severe hemoptysis and died. This case illustrated the potential dangers of expectant treatment. Small foreign bodies in the wall of the heart and in the hilus of the lung are well tolerated. It is advisable not to remove them, especially from the hilus, because of the risk of uncontrollable hemorrhage. Foreign bodies which are in one of the cavities of the heart should be removed regardless of the operative risks. Large foreign bodies should always be extracted, no matter where they are located in the heart or mediastinum. In general Professor Le Fort felt that his good end results justified the recommendation that an early operation was indicated.

The second paper was by Dr. Petit de la Villéon, warmly advocating removal of shell fragments and similar bodies under radioscopic control, but he was less radical in stating the indications for operation in cases of injury to the heart. In his opinion projectiles freely mobile in the cavities of the heart as well as those embedded in the wall of the auricles and right ventricles should not be removed. In the case of projectiles in the wall of the left ventricle, only those lying near the apex should be extracted and then only if at least 6 mm. of cardiac muscle is interposed between the ventricular cavity and the projectile.

Public Health Service for 1937

The public health department of the ministry of the interior has published its report for 1937, a few months after the close of the year. The rapid assembly of so large a body of data must have entailed a vast amount of work. In the interests of expedition a preliminary report was issued, in which the more important observations are summarized; a few of these are herewith cited.

The number of marriages has increased ever so slightly, although the less numerous "war baby group" are now reaching the marriage age. The increase in the natality appears at present to have come to a standstill; a particular decline was conditioned by the influenza epidemic in the winter of 1936-1937. The number of births of second children has further increased by from 7,000 to 8,000 and the number of births of third children by from 5,000 to 6,000. The mortality seems to have remained on the whole fairly stationary during 1937, despite a manifest decline in the number of deaths from several specific causes. This constancy of the mortality is to be evaluated as a noteworthy advance, since it signifies an increase in the numbers of the higher age groups. The number of

persons over the age of 60 increases yearly by more than 200,000; the proportion of this group to the population of the reich increases yearly by around 2 per thousand. Nursing mortality as well as the number of stillbirths has declined somewhat further. The fluctuations observed in the various causes of death among nurslings are interesting. In table 1 are set forth the number per thousand of living births and of deaths from various causes in the first year of life in the larger German cities.

TABLE 1.—Causes of Death

Year	Premature Birth	Non-viability	Premature Birth and Nonviability Combined	Endo-enteritis	Syphilis
1935	16.62	16.46	33.58	5.90	0.58
1936	17.21	15.83	33.04	5.41	0.31
1937	16.87	15.13	32.00	5.72	0.21

Fatal syphilis of nurslings has become rare; its steady decline points to a recession of syphilis among mothers and among the population as a whole. A principal factor in the decline of nursing mortality is the diminution in the number of deaths from premature birth and nonviability (including malformations and obstetric accidents). Except in 1934 a decline of this type of early mortality formerly contributed scarcely at all to the decline of nursing mortality in general.

The figures for infectious diseases of childhood are also of interest. Those for the larger German cities are summarized in table 2.

TABLE 2.—Fatalities from Various Diseases of Childhood

Year	Diphtheria	Scarlatina	Measles	Whooping Cough
1935	2,560	342	337	320
1936	2,340	359	294	789
1937	1,800	290	274	488

Statistics for the entire reich on diphtheria and scarlatina are shown in table 3. After a progressive increase over several years, the incidence reached a high point in 1936 and declined during 1937, although the decrease in the number of cases of diphtheria was slight indeed. At the same time the mortality from both diseases underwent a decline in 1937 which was especially evident in the larger cities. The end of the year, however, brought with it an increase in these infections which surpassed the corresponding figures for the end of 1936.

TABLE 3.—Statistics for Diphtheria and Scarlatina

Year	Diphtheria			Scarlatina		
	No. of Cases	Morbidity per 10,000 of Population	Mortality per 100 Cases	No. of Cases	Morbidity per 10,000 of Population	Mortality per 100 Cases
1935	132,930	19.9	4.4	111,648	16.7	0.72
1936	147,629	22.0	3.8	123,874	18.5	0.72
1937	146,733	21.8	3.7	117,544	17.5	0.70

The incidence of acute anterior poliomyelitis has increased. The number of cases reported was 2,080 in 1935, 2,256 in 1936 and 2,723 in 1937. The morbidity per 10,000 of population rose from 0.31 to 0.40. The mortality per hundred cases amounted to 8.8 in the year 1935, 9.5 in 1936 and 11.9 in 1937. In the epidemic year 1932, nearly 4,000 cases were reported. The mortality from tuberculosis, which has shown an almost uninterrupted recession for many years, continued to decline during the past few years in the larger cities of Germany. In 1937 the rate was 6.9 per 10,000 of population, a new all time low. This recession has to do chiefly with pulmonary

tuberculosis. Statistics on lupus are now for the first time officially reported; the number of cases in the reich was 1,042; namely, 0.15 per 10,000 of population.

The incidence of typhoid, on the decline for several decades, increased slightly during 1937 (3,051 cases, against 2,894 in 1936), but this may be regarded as of no significance. Only the morbidity increased, not the mortality. The incidence of paratyphoid has in recent years approximated that of typhoid (about 3,000 cases annually). Conversely, the paratyphoid mortality (from 3 to 4 per cent) is only one third that of typhoid (the latter is from 10 to 11 per cent). The influenza morbidity was only 1.3 per 10,000 of population, against 1.9 in the year 1936 and 1.6 in 1935. Ninety cases of anthrax were reported as against sixty-eight in 1936. Twenty-two persons were taken ill with psittacosis, six of them fatally (as against fifty-three cases and eleven fatalities in 1936). No cases were reported of rabies, cholera, typhus, plague, smallpox or trichinosis. An increase was noted in the number of persons dying of cancer, diabetes, apoplexy and paralysis, heart disease and senile debility.

The incidence of suicides has remained unchanged (about 6,200 yearly). The number of accidental deaths per 10,000 of population has increased from three in the year 1935 to 3.3; namely, from 6,142 to 6,851. Chiefly responsible for the last-mentioned circumstance is the increase in the number of industrial plants and not the greater motorization of traffic; in fact, the number of street traffic accidents decreased in 1937.

The general state of national health and nutrition was considered satisfactory. There are a few exceptions, however. It is reported, for example, that because the peasants of Bavaria are reluctant to take advice and distrustful of the modern methods of nutrition, there is still a high incidence of nutritional disturbances, partly of a serious nature, among the nurslings of the region. Repeated reference is made to the dangers inherent in the increasing misuse of tobacco by the youth. The housing shortage has become exacerbated, owing to the immigration into industrial areas and the utilization of existing buildings for other than residential purposes. In particular there is a lack of dwellings of the smaller and smallest sizes, and many persons are still housed in structures such as barracks and shanties. The number of abortions declined during 1937.

At the end of 1937 there were 744 health departments in the German reich; of these, 655 were classed as federal boards under a national director, fifty as communal under a national director and thirty-nine as communal under a communal director. There were ninety-five special departments of eugenics and racial hygiene and twenty-seven bureaus devoted to other special fields. There were 22,265 persons in the employ of health departments, 10,701 (48 per cent) of them full time employees. About one third of the total personnel and more than one half (56.5 per cent of the full time personnel were women). Altogether 7,218 physicians were in the service of health departments. They serve as specialists in a great diversification of fields, principally pulmonary diseases, pediatrics, orthopedics, dermatology and venereology.

Advice with regard to marriage was dispensed to about 450,000 persons; namely, about 36 per cent of persons contracting marriage. About 30 per cent of all persons marrying received a governmental subsidy. Advice was dispensed to about 95,000 pregnant women; namely, about 7 per cent of the total. The number of special welfare centers for nurslings and young children was about 16,000. Advice was given with regard to the care of 1.25 millions of nurslings. More than 500,000 infants were entrusted to the health services. There were 276 school physicians on full time service and 4,477 not on full time. About 3.25 millions of school children underwent group physical examination. There were 5,146 school dentists (191 on full time, 4,955 not on full time). The health depart-

ments operated 1,477 special antituberculosis centers, as well as 456 similar establishments; these centers advised 1.25 millions of persons and made roentgenoscopic studies of an equal number and roentgenograms of 190,000. They sent 45,000 patients to sanatoriums and more than 14,000 to hospitals. The advisory centers for patients with venereal disease were 814 in number and dispensed advice to 200,000 persons. There were 420 advisory centers for orthopedic cases, at which 170,000 persons sought advice. There were twenty-four special advisory centers for patients with cancer and 285 other centers at which such patients received advice; 12,000 persons passed through these centers.

AUSTRALIA

(From Our Regular Correspondent)

June 29, 1938.

State Medicine in New Zealand

New Zealand is at present in the throes of working out a health insurance scheme to cover every member of the community. This scheme when it becomes law will mean the control of the medical profession by the state. To appreciate the medical situation in New Zealand, it is necessary to be acquainted with the general political background. New Zealand has been described as a totalitarian democracy. The declared policy of the present labor government is socialistic. As soon as it took office in 1935, legislation was introduced to give effect to election promises of increased wages and shorter hours and to lay the foundations for a completely socialistic state. Railways, public works, post and telegraph services, the police departments, electric power and all transport are now administered by the government. State control of the whole of the dairying industry has been established, housing schemes have been instituted, the national radio service has been placed completely under the control of a minister for broadcasting, and the establishment of a state iron and steel industry has just been authorized. For the government to complete its promises, it remains for it to introduce a national health insurance and superannuation bill before the next election, at the end of this year. The proposals are now being considered by a special parliamentary committee.

The scheme will be universal and will include dependents as well as wage earners, irrespective of income. At first only general practitioner and maternity services will be provided. Specialists and consultants will be brought in at a later date. General practitioners on the whole are enthusiastic about the scheme but specialists are opposed to it. The official criticisms of the British Medical Association in New Zealand are directed chiefly against the universal nature of the plan. To a socialist government, however, it is fundamental that a scheme should provide equal service for everybody. Only in this way can the division of patients into two classes be abolished, thus enabling doctors to give of their best to every one, without keeping an eye on the bank balance. The new schemes are to be financed partly by an increase in the wages tax of eightpence to 1 shilling in the pound, and what is now known as the unemployment tax will become the social security contribution. This will be subsidized on a pound for pound basis out of general government funds. At present it appears that some difficulty has been encountered in the progress of the scheme. This is probably financial rather than medical. Many people in New Zealand doubt the workability of the plan, and the actuary who carried out the preliminary calculations, now convinced of the inability of the scheme to function successfully, has resigned his position and left New Zealand.

Free Medical Service for Tasmania

Tasmania is experimenting in the formation of a state medical service which is freely available to all. Local authorities have been so impressed with the scheme that, in addition to the eight districts where it has been decided to place state

physicians, many other areas are negotiating with the government for a similar provision. The first physician appointed took up duties March 1. The original proposal provided for placing physicians in districts remote from medical aid, but in view of the fact that in many districts the administration of the local public health services was very casual the government decided to utilize the services of these as public officers. The state physicians to be located in these districts will be officers of the public health department and subject to its control. Each appointment carries a salary of from £600 to £850 per annum, according to the duties of the office and the area to be served, a house allowance of £50 per annum, and a gratuity subject to satisfactory service of £50 per annum payable at the termination of three years. Officers will be allowed one month's leave annually for a hospital refresher course and one month's annual leave on full pay.

The duties of the district health officers will include investigations into problems of sanitation, control of infectious diseases, regular and systematic inspection of all school children, control and protection of food supplies, supervision of private hospitals, the work of industrial hygiene and education of the public in the principles of public health and personal hygiene. Medical services will be free to all between specified hours at the physician's place of location and on his visiting days at various centers of population in the district. Except for his consulting hours at his place of residence and his visiting days to other centers, he will be permitted to charge and retain a consulting fee and to charge at the rate of sixpence per mile for motor car mileage. In the absence of such charges it is felt that free medical service would be abused by certain of the community. Medical attendance in maternity cases will also be free if patients are confined in either a private maternity home or a bush nursing hospital. If a district in which a physician is placed possesses either of these facilities and the patient does not utilize them, she shall be required to pay a fee for medical attendance, the object being to encourage mothers to utilize the hospital services in the interests of maternity and child welfare. Local committees of three will be constituted as a connecting link between the department and the local authority.

Placental Infection During Induced Labor

The many reports in the literature of *Bacillus coli* infections of the newborn and the frequency with which infection of the placenta by coliform organisms is associated with stillbirth and neonatal death have led Penfold and Butler of the Baker Institute of Medical Research, Melbourne, to believe that such infections of the newborn frequently arise from the contaminated placenta while the fetus is still in utero. They consider, moreover, that the surgical induction of labor may be important in such occurrences. They have reported the results of the bacteriologic examination of 114 placentas; in forty-six cases labor had been induced with the rectal tube, and in the remainder surgical induction had not been practiced. Placental infection was detected 2.5 times more often in the cases of surgical induction than in the other cases. More striking still was the difference in the nature of the infection. In the cases of tubally induced labor, *B. coli*, aerobic nonhemolytic streptococci and *Bacillus welchii* in the placenta were common. Mixed infections were also frequent. In cases of normal labor the placentas did not show any organisms of a characteristic fecal type, nor did they show any mixed infections. A prolonged interval between the induction of labor and the delivery of the child was found to increase the risk of infection of the placenta. Infection does not appear to be dependent to any great extent on the maternal condition or on the age of the fetus.

A high correlation was noted between placental infection and death of the child, mixed infections of the placental tissue and infections of the large fetal vessels of the placenta being especially serious for the infant. When the child was stillborn or

died within ten days of birth, cultures similar to those made from the placenta were made from the heart's blood, spleen and lung and occasionally from the liver. Bacteria cultivated from these tissues were usually similar to those obtained from the placenta. When additional organisms are present in the fetus, their source is probably an infected liquor amnii. When *B. coli* was found in the placenta and in the body of the dead infant, the strains isolated were shown to be biochemically and serologically identical, suggesting a single disease process. A high correlation was observed between placental infection and maternal morbidity.

Marriages

WILBUR DEXTER JOHNSTON, New Haven, Conn., to Miss Susan Elizabeth Merritt of Americus, Ga., July 23.

CLARKE PAUL PENNINGTON, Vanceburg, Ky., to Miss Marjorie Marie Burns of Chattanooga, Tenn., recently.

ROBERT OWEN CANADA JR., Charlottesville, Va., to Miss Julia Dent Salter of Anniston, Ala., in July.

CARROLL VANCE WILLIS, Morehead City, N. C., to Miss Norma Lucile Askew at Snow Hill, June 5.

FLORENCE SULLIVAN HASSETT, Elmira, N. Y., to Miss Eleanor Rosalie Bingham at Saranac Lake in July.

GEORGE WILLIAM HERLITZ, Corona, N. Y., to Miss Muriel Kingdon Hellwig of Elmhurst, June 27.

FRANCIS BURTON BLACKMAR, Columbus, Ga., to Miss Elizabeth Ann Standard of Tignall, July 10.

ROBERT PEYTON VINCENT JR., Yazoo City, Miss., to Miss Jane Haas of New Orleans, July 20.

JAMES WILLARD COOMBS, Camden, Ohio, to Dr. CHARLOTTE M. JOHNSON of Cincinnati, June 11.

GLEA VAUGHN STANTON, Limestone, Tenn., to Miss Cleo Dell Johnson of Memphis, July 17.

HAROLD LAWTON ROGERS, Albertville, Ala., to Miss Frances McKenzie in Fulton, Ky., in July.

JOHN WILLIAM BICK, New Orleans, to Miss Minnie Martha Walters in Biloxi, Miss., July 1.

KENNETH FRANKLIN HUGHES, Irving, Ill., to Miss Edna Doris of Mattoon, Ill., June 14.

THOMAS L. DOYLE, Philadelphia, to Miss Elizabeth Emerson of Bala-Cynwyd, Pa., July 5.

FRANK THOMPSON, Tanta, Egypt, to Miss Helen Day of East Orange, N. J., in July.

WILLIAM BRUCE NELSON, Fairfield, Ala., to Miss Edith Monroe of Marvel recently.

JAMES MAXEY DELL, Gainesville, Fla., to Mrs. Rose H. Eddins of New York, July 6.

MAURICE H. WEINSTEIN, Middletown, Ohio, to Miss Mary L. Morrical of Oxford in July.

JAMES WESLEY MCKINNEY to Miss Eleanor Trezevant, both of Memphis, Tenn., July 20.

JOHN J. McDONOUGH to Miss Marie Alberta Nelson, both of Youngstown, Ohio, in July.

LA VERNE WILSON SWIGERT, Boston, to Miss Marjorie Helm of Evanston, Ill., July 23.

HOMER LAMAR HOWARD to Miss Dela Inez Bailey, both of Winona, Miss., in June.

ALEXANDER BRADFIELD, Detroit, to Miss Elda Mae Reese of Seaside, Ore., in July.

LYNN W. WHELCHER to Miss Margaret A. Peters, both of Miami, Fla., June 18.

ALONZO LEE BEST, Newport, Ark., to Mrs. Norma Masters of Jonesboro, July 1.

ROBERT D. BICKEL, Roanoke, Va., to Miss Louise Bigony of Baltimore in June.

RUBEN B. BAUGH, Polkville, Miss., to Miss Flora Walrod in Raleigh, July 17.

MILTON M. ABELES to Miss Dorothy Cohen, both of New York, July 23.

BORIS PETROFF to Miss Ruth Gibbons, both of New York, July 25.

ZACHARY A. BLIER to Miss Evelyn Nauman, both of Chicago, July 7.

Deaths

Frank Douglas Phinney ☉ Cincinnati; University of Pennsylvania Department of Medicine, Philadelphia, 1899; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; on the staffs of the Bethesda Hospital and the Children's Convalescent Home of the Cincinnati Orphan Asylum and the St. Anthony Hospital, International Grenfell Foundation, Newfoundland; aged 64; died, May 30, of arteriosclerotic heart disease.

Robert Effinger Cumming ☉ Detroit; Columbia University College of Physicians and Surgeons, New York, 1917; member of the American Urological Association; fellow of the American College of Surgeons; aged 43; on the staffs of the Receiving Hospital, Grace Hospital, St. Joseph's Mercy Hospital, Highland Park General Hospital, the United States Marine Hospital and the Charles Godwin Jennings Hospital, where he died, June 23, of cirrhosis of the liver.

Joseph Pomeroy Widney, Los Angeles; Toland Medical College, San Francisco, 1866; also a minister; member of the California Medical Association; Civil War veteran; a founder and past president of the College of Medicine of the University of Southern California and dean and professor of medicine on its faculty for many years; was a member of the state board of health; for many years member of the city board of education; aged 96; died, July 4.

Wendell Stewart ☉ East St. Louis, Ill.; Washington University School of Medicine, St. Louis, 1930; member of the Radiological Society of North America; on the staffs of the Christian Welfare Hospital and St. Mary's hospitals, East St. Louis, and St. Elizabeth's Hospital, Belleville; aged 34; died, June 6, in the Barnes Hospital, St. Louis, following an operation for removal of a brain tumor.

James William Roberts, Atlanta, Ga.; Atlanta College of Physicians and Surgeons, 1913; member of the Medical Association of Georgia; assistant professor of clinical surgery at the Emory University School of Medicine; served during the World War; aged 52; on the staffs of the Crawford W. Long Hospital and the Emory University Hospital, where he died, May 4, of carcinoma of the lungs.

John Raymond Lehmann, Dallas, Texas; University of Pennsylvania Department of Medicine, Philadelphia, 1911; member of the State Medical Association of Texas; emeritus professor of therapeutics at the Baylor University College of Medicine; aged 58; died, May 30, in the Baylor Hospital, of cardiac decompensation, hypertension and left hemiplegia.

Josiah Travilla Bunting, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1894; assistant in otology, 1920-1924, and later instructor, Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; veteran of the Spanish-American and World wars; aged 69; died, May 31, of cerebral hemorrhage.

John William McConnell, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; member of the Illinois State Medical Society; on the staff of St. Anne's Hospital; aged 64; died, May 10, in the Sacred Heart Sanitarium, Milwaukee, of coronary thrombosis.

Davidson Ker Texada, Alexandria, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1897; member of the Louisiana State Medical Society; formerly mayor; on the staff of the State Colony and Training School; aged 59; died, May 26, of coronary thrombosis.

Amos Carter, Indianapolis; Indiana Medical College, Indianapolis, 1878; member of the Indiana State Medical Association; at one time superintendent of the Indiana State Sanatorium, Rockville, and the Indiana Boys School Hospital, Plainfield; aged 85; died, May 30, of chronic myocarditis.

William R. Newton ☉ Cameron, Texas; Memphis (Tenn.) Hospital Medical College, 1899; past president of the Milam County Medical Society; state senator; fellow of the American College of Surgeons; part owner of the Cameron Hospital; aged 64; died, May 21, of coronary thrombosis.

Charles Lee Bailey, Hudson Falls, N. Y.; New York Homeopathic Medical College, New York, 1891; member of the Medical Society of the State of New York; veteran of the Spanish-American and World wars; aged 68; died, May 8, in a hospital at Albany of pneumonia.

William L. Starr, New Albany, Ind.; University of Louisville (Ky.) Medical Department, 1881; member of the Indiana State Medical Association; formerly county coroner and secretary of the city board of health; aged 79; died, June 4, of chronic myelitis and myocarditis.

Gabriel Eugene Tenaglia, Honey Brook, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1929; member of the Medical Society of the State of Pennsylvania; aged 33; died, June 10, in the Bryn Mawr (Pa.) Hospital, of carbon monoxide poisoning.

Amzi Weaver, New Albany, Ind.; Kentucky School of Medicine, Louisville, 1904; member of the Indiana State Medical Association; formerly superintendent of county schools; aged 64; died, June 6, of hypostatic pneumonia and cerebral embolus.

George L. Hume, Sherbrooke, Que., Canada; McGill University Faculty of Medicine, Montreal, 1898; fellow of the American College of Surgeons; surgeon to the Sherbrooke Hospital; aged 69; died, May 30, of coronary thrombosis.

Henry Hulse Seibert, Davis, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; aged 70; died, May 1, in the Evangelical Hospital, Freeport, of heart disease and pneumonia.

Prince Wolverton Byrd, Salem, Ore.; Willamette University Medical Department, Salem, 1911; on the staff of the Salem State Hospital; aged 53; died, May 30, in the Salem General Hospital of coronary thrombosis.

Fred Colman Nichols ☉ Santa Monica, Calif.; St. Louis University School of Medicine, 1904; on the staff of the White Memorial Hospital, Los Angeles; aged 56; died, May 27, in Glasgow, Scotland, of acute meningitis.

Austin F. Robinson, Baltimore; Southern Homeopathic Medical College, Baltimore, 1903; on the staff of the Union Memorial Hospital; aged 67; died, May 15, in Ruxton, Md., of lymphosarcoma and bronchopneumonia.

Thomas Aaron Klingensmith, Jeannette, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1890; member of the Medical Society of the State of Pennsylvania; aged 73; died, May 27, of cerebral hemorrhage.

Carl Emil Becker ☉ Philadelphia; Temple University School of Medicine, Philadelphia, 1912; formerly on the staff of the Lankenau Hospital; aged 76; died, May 9, of injuries received in an automobile accident.

Cortlandt William Dawe, Forest Hills, N. Y.; Cincinnati College of Medicine and Surgery, 1901; served during the World War; aged 56; died, April 1, in the Lewistown (Pa.) Hospital of pulmonary edema.

Thomas Cleaborn Bullock, Autryville, N. C.; College of Physicians and Surgeons, Baltimore, 1885; member of the Medical Society of the State of North Carolina; aged 74; died, May 27, of heart disease.

Harley Emmett Keyes, Pasadena, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; aged 61; died, May 22, of poison, self administered.

Charles Wesley Reed ☉ Grand Junction, Colo.; American Medical College, St. Louis, 1905; on the staff of St. Mary's Hospital; aged 62; died, May 31, in St. Anthony Hospital, Denver, of coronary thrombosis.

Henry C. Smith, Hackensack, N. J.; New York Homeopathic Medical College, New York, 1874; aged 85; died, June 6, in the Hackensack Hospital of pulmonary edema following strangulated hernia.

Henry Franklin Staples, Cleveland; Cleveland University of Medicine and Surgery, 1896; on the staff of the Huron Road Hospital, East Cleveland; aged 68; died, May 26, of retroperitoneal sarcoma.

David H. Oliver, Bridgeton, N. J.; Jefferson Medical College of Philadelphia, 1888; member of the Medical Society of New Jersey; aged 83; died, May 2, of cerebral hemorrhage and arteriosclerosis.

Charles Sylvester Mellen, Peoria, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; aged 58; died, May 25, of chronic myocarditis.

William Hackett Hines ☉ Kansas City, Mo.; University Medical College of Kansas City, Mo., 1912; aged 53; on the staff of St. Luke's Hospital, where he died, May 26, of cerebral hemorrhage.

Donald Wolpert Ward, Denver; University of Colorado School of Medicine, Denver, 1931; on the staff of the National Jewish Hospital; aged 34; died, May 18, in a local hospital of pneumonia.

Ellen Harris Heise, Huntington Park, Calif.; Northwestern University Woman's Medical School, Chicago, 1887; aged 90; died, April 13, of bronchopneumonia and arteriosclerosis.

Lloyd Moffitt ☉ Yakima, Wash.; University of Pennsylvania School of Medicine, Philadelphia, 1909; served during the World War; health officer; aged 53; died, May 2, of gastric carcinoma.

Charles Fischer Nall, Birmingham, Ala.; Meharry Medical College, Nashville, Tenn., 1918; aged 48; died, May 8, in the Provident Hospital, Chicago, of hypertension and nephrosclerosis.

Louis Max Turbin, Chicago; Chicago Homeopathic Medical College, 1891; aged 80; died, May 9, in the Ravenswood Hospital of injuries received when he was struck by a street car.

Allen J. Mason, Friendsville, Md.; Jefferson Medical College of Philadelphia, 1884; district school trustee and at one time mayor; aged 80; died, May 30, of coronary occlusion.

Lola Delores Clark Mighell Kenderdine, Des Moines, Iowa; State University of Iowa College of Medicine, Iowa City, 1894; aged 67; died, May 11, of coronary heart disease.

Joseph A. Harper, Wellston, Ohio; Columbus Medical College, 1892; formerly member of the city board of education; aged 78; died, May 19, of acute dilatation of the heart.

Joel Carl Dodson, Carthage, Miss.; Chattanooga (Tenn.) Medical College, 1905; Mississippi Medical College, Meridian, 1907; aged 57; died, May 15, of cerebral hemorrhage.

Xavier Dodel, San Francisco; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1882; aged 83; died, May 1, of coronary thrombosis.

Arthur Samuel Cornell, Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; aged 65; died, May 28, of coronary thrombosis.

John Q. A. Clowes, Shelby, Ohio; Philadelphia University of Medicine and Surgery, 1869; aged 93; died, May 24, of organic heart disease and gangrene of the left foot.

Bertram Cameron Blackhall, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1935; intern at the Toronto General Hospital; aged 28; died, June 8.

Clinton Homer Day, Clarksville, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1900; aged 61; died, May 15, of cerebral hemorrhage and heart disease.

Henry A. Schneider, Owatonna, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; aged 61; died, May 7, of coronary sclerosis.

William E. Krumstiek, Granite City, Ill.; Hahnemann Medical College and Hospital, Chicago, 1891; aged 78; died, May 24, of myocarditis and mitral stenosis.

Thomas Frank Miles, Lorena, Texas; Tulane University of Louisiana Medical Department, New Orleans, 1884; aged 80; died, May 7, of carcinoma of the kidney.

Chalmers Craig, Johnstown, Pa.; Western Reserve University Medical Department, Cleveland, 1900; aged 67; died suddenly, April 5, of cerebral hemorrhage.

Stuart M. Yancey, Gainesville, Fla.; College of Physicians and Surgeons, Baltimore, 1886; aged 73; died, May 20, of arteriosclerosis and cerebral hemorrhage.

Jessie F. Buckley Ogden Seger, Wichita, Kan.; Keokuk (Iowa) Medical College, 1892; aged 76; died, May 24, in a local hospital of arteriosclerotic heart disease.

John Bell Fraser, Toronto, Ont., Canada; Trinity Medical College, Toronto, and Queen's University Faculty of Medicine, Kingston, 1888; aged 82; died, May 25.

George W. Toney, Piedmont, Mo.; St. Louis Medical College, 1880; member of the Missouri State Medical Association; aged 83; died, May 15, of heart disease.

Patrick S. Humphrey, Ashland, Ky.; University of Louisville Medical Department, 1891; aged 69; died, May 10, of arteriosclerosis and pernicious anemia.

William S. Williamson, Galesburg, Ill.; Jefferson Medical College of Philadelphia, 1889; Civil War veteran; aged 91; died, May 20, of cerebral hemorrhage.

James Henry Hatfield, Indianapolis; Hospital College of Medicine, Louisville, Ky., 1897; aged 64; died, May 10, of myocarditis and cerebral hemorrhage.

John Bell Dinsmore, Hillsboro, Ore.; University of Oregon Medical School, Portland, 1910; served during the World War; aged 55; died, May 5, of myocarditis.

Elisabeth Dehn Bayer, Agnew, Calif.; Northwestern University Woman's Medical School, Chicago, 1898; aged 70; died, May 26, of carcinoma of the uterus.

Erle W. Horswill, Palo Alto, Calif.; Eclectic Medical Institute, Cincinnati, 1908; aged 55; died, May 25, of lethargic encephalitis and bronchopneumonia.

Edward James Comerford, Pittsburgh; National Medical University, Chicago, 1909; also a pharmacist; aged 57; died, May 20, of cerebral hemorrhage.

Preston Theodore Rhoads, Howell, Tenn.; Vanderbilt University School of Medicine, Nashville, 1890; aged 75; died, May 7, of cerebral hemorrhage.

Elmer Thomas Davis, Modesto, Calif.; University Medical College of Kansas City, Mo., 1903; aged 70; died, May 9, of arteriosclerotic heart disease.

Aris D. N. Whitley, Monroe, N. C. (licensed in North Carolina in 1897); aged 63; died, May 31, in a hospital at Charlotte of aplastic anemia.

John H. Goggins, Jacksonville, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1916; aged 58; died, May 12, of diabetes mellitus.

William M. Smith, Van Wert, Ohio; Columbus Medical College, 1880; formerly deputy postmaster; aged 80; died, May 14, of cerebral hemorrhage.

Franz Emory Solier ☉ Bryan, Ohio; Long Island College Hospital, Brooklyn, 1907; aged 53; died, May 4, in a hospital at Toledo of acute hepatitis.

Esaías Nordgren, Des Moines; College of Physicians and Surgeons, Keokuk, Iowa, 1898; aged 68; died, May 17, of carcinoma of the left lung.

Duncan D. McCallum, New Dayton, Alta., Canada; University of Toronto Faculty of Medicine, Toronto, Ont., 1896; aged 71; died, May 6.

James William Webb, Hedley, Texas; Memphis (Tenn.) Hospital Medical College, 1903; aged 55; died, April 15, of coronary thrombosis.

Robert Richey, Hollister, Calif.; Marion-Sims College of Medicine, St. Louis, 1892; aged 71; died, April 1, of acute coronary thrombosis.

James L. McDowell, Central City, Ky.; Louisville Medical College, 1890; formerly mayor; aged 78; died, May 7, of cerebral hemorrhage.

John Ferrell Wood, Manitou, Man., Canada; Manitoba Medical College, Winnipeg, 1914; aged 52; died, May 7, of coronary thrombosis.

Kate Frances Ozmun Phillips, Shaker Heights, Ohio; Cleveland Medical College, 1893; aged 66; died, April 16, of cerebral hemorrhage.

Aaron Welch Edmiston, Omaha; Rush Medical College, Chicago, 1880; aged 81; died, May 29, of coronary thrombosis and arteriosclerosis.

Charles Hugh Wilcox, Fitzgerald, Ga.; Atlanta College of Physicians and Surgeons, 1901; aged 63; died, May 17, of coronary occlusion.

Gaston Edward Dudley, New Bern, N. C.; Meharry Medical College, Nashville, Tenn., 1928; aged 38; died, May 15, of cardiorenal disease.

Thomas Spotuas Burwell, Philadelphia; Jefferson Medical College of Philadelphia, 1907; aged 61; died, April 19, of coronary embolus.

James J. Upshaw, Hartsville, Tenn.; University of Louisville (Ky.) Medical Department, 1878; aged 80; died, May 7, of pernicious anemia.

Jesse Benjamin Manor, La Center, Ky.; Missouri Medical College, St. Louis, 1882; aged 83; died, May 20, of carcinoma of the prostate.

Roy Carlton Glann ☉ Bronson, Iowa; Sioux City College of Medicine, 1905; aged 59; died, May 24, of carbon monoxide poisoning.

Walter W. Fugitt, St. Petersburg, Fla.; Kentucky School of Medicine, Louisville, 1892; aged 72; died, May 13, of coronary occlusion.

Charles H. Martin, Baltimore; University of Denver Medical Department, 1885; aged 77; died, May 13, of chronic nephritis.

Arthur Thaddeus Perry, Camden, Tenn.; Mississippi Medical College, Meriden, 1910; aged 58; died, May 11, of heart disease.

Morgan M. Lane, Harviell, Mo.; Missouri Medical College, St. Louis, 1882; aged 80; died, May 4, of cerebral hemorrhage.

Alexander M. Tait, Blakesburg, Iowa; Keokuk Medical College, 1892; aged 86; died, May 28, in Wapello of senility.

Correspondence

NOMENCLATURE IN ACUTE POLIOMYELITIS

To the Editor:—The simple diagnostic term "poliomyelitis" (meningo-encephalopolyomyelitis) fails to portray different forms of a disease notable for the extreme variability of its clinical appearance. Recently the modifying terms "abortive," "non-paralytic," "preparalytic" and "paralytic" have been employed to designate the stage or severity of the disease. These terms are also vague and confusing. A diagnosis of "abortive" poliomyelitis is presumptive, without means of confirmation. Even if the virus is found in the nasopharynx or rectal washings in such "abortive" cases, it is still only an assumption that the virus was the causative agent of the indefinite illness, since healthy carriers have been described. The term "preparalytic" is objectionable because it conveys the idea that paralysis would inevitably ensue. Statistical studies have disclosed that such an outcome is not the rule. To avoid the use of "preparalytic," the term "nonparalytic" has been proposed. The term "non-paralytic" cannot be applied to an acute case of poliomyelitis because the development of paralysis, while not the rule, is only too frequent an outcome. Although the term "paralytic" is least objectionable, it too loses its value and is inaccurate as it is used at present to describe all cases with clinical motor involvement, from slight to extensive paralysis.

The term "epidemic poliomyelitis" should be definitely reserved to designate a disease produced by a distinctive virus. We recognize a definite clinical picture, which is correlated with the degree and extent of pathologic alterations in the spinal cord. The clinical diagnosis of "poliomyelitis" at present is based on (a) the prodromal signs and symptoms, which include headache, neck and back rigidity, and so on and (b) confirmatory and characteristic spinal fluid manifestations, which may or may not be associated with (c) muscle weakness or paralysis. The term "poliomyelitis" fails to convey any information other than the diagnosis, because of the fact that the disease is so variable.

The requirements of an ideal classification are to convey both an accurate picture of each case and the prognosis. The only method of accomplishing such an aim in this disease is by careful muscle examination and observations on the stage of the illness. We therefore propose the following classification for acute cases of poliomyelitis:

Stage	Degree	Extent
Early Late	without paralysis with slight paralysis with moderate paralysis with severe paralysis with bulbar paralysis and paralysis	of extremity and muscle groups involved

A case will be one of "acute poliomyelitis" if the patient presents the symptoms enumerated above and is acutely ill.

The period of acute illness lasts from one to seven days, the average being four days. In general, a case in the first forty-eight hours of illness if paralysis is not present, or in the first twelve if paralysis exists, may arbitrarily be designated as "early acute." Thereafter it may be called "late acute." If any form of specific therapy is to be employed, it is probable that results will be modified by the stage of the disease in which the treatment is instituted.

The degree and extent of clinical paralysis can be determined only by a comprehensive muscle examination. Arbitrary standards must be selected here because of the individual variations which prevent the establishment of clearcut groups:

1. "Without paralysis" needs no discussion.

2. "With slight paralysis" should include patients in whom the involved muscles are capable of carrying out all active movements against gravity but in whom muscle power is so impaired that it is insufficient to overcome resistance offered by the examiner.

3. "With moderate paralysis" should be used to designate a degree of involvement in which good muscle contraction exists, so that partial to complete movement can be accomplished only when friction and gravity are removed.

4. "With severe paralysis" should include those cases in which muscle power is so diminished that no movement can be performed.

The extent of involvement can be indicated by stating the extremity and muscle groups involved, e. g. foot flexors, arm abductors, hip abductors.

A classification of this kind is more cumbersome, but it conveys a more accurate conception of the stage, nature and severity of the illness. Such a standard classification, if followed, lays the foundation for comparisons between epidemics in different places and at different times and might be of value in clarifying the effects of therapeutic measures. We believe that, in general, prognosis can be predicated from the use of such a classification; e. g., late acute poliomyelitis without or with slight paralysis usually make a good recovery, while patients acquiring a severe paralysis early in the illness have a poor outlook for significant recovery.

It should be pointed out that patients with poliomyelitis who have had subsidence of fever and other acute symptoms are no longer in the "acute" stage but are convalescent. Such "convalescent" cases should not be classified as suggested in the tabulation. They belong in a group which may be called "convalescent poliomyelitis," and the extent of the (then) final paralysis can be noted.

SIDNEY O. LEVINSON, M.D.

PAUL H. HARMON, M.D.

Chicago.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

GLAUCOMA AND COFFEE

To the Editor:—What is the present opinion regarding the use of tobacco, alcohol, coffee or tea for a patient with simple chronic glaucoma? I first noted trouble with reading about two years ago and went to several eye men, all of whom prescribed stronger glasses. The diagnosis of glaucoma was eventually made and pilocarpine prescribed. The first night of taking it I suffered an acute attack with all the textbook symptoms. About eight months ago I underwent an operation on my left eye (iridectomy) and later had a troublesome iritis striata. I am now using pilocarpine in moderation and have no trouble aside from an occasional attack of orbital pain, which usually yields to 20 grains (1.3 Gm.) of acetylsalicylic acid. I am still greatly troubled by the halos around lights and the only way I can shut them out is to instil sufficient pilocarpine to give me a pinpoint pupil. Wearing dark glasses only gives me more pain and lacrimation later. My pressure is now around 16 to 18. Will Sanka coffee hurt me?

M.D., New York.

ANSWER.—Opinion is not unanimous in the ophthalmologic profession as to the effect of stimulants such as tobacco and coffee on a glaucomatous eye. It is believed that such stimulants have a decided tendency to increase intra-ocular pressure, probably by vasodilatation within the iris and ciliary body. In fact, one of the provocative tests in eyes suspected as preglaucomatous is to have the patient drink two large cups of strong black coffee and then note the effect on the tension tonometrically registered. In possibly 15 per cent of the cases there is an increase in pressure of from 10 to 25 mm. of mercury within fifteen minutes. Consequently the average modern ophthalmologist warns his glaucomatous patients to abstain from coffee except in small amounts.

ALOPECIA AREATA

To the Editor:—A man, aged 27, in excellent general health, has had for many years two small hairless spots on the bearded region of his face. Last June they began to spread and similar areas appeared on his scalp. Complete physical examination and urinalysis were entirely negative. The basal metabolism was minus 14, so that thyroid in gradually increasing doses up to 3 grains (0.2 Gm.) daily was given for a time. The local lesion was diagnosed as alopecia areata by a competent dermatologist and treated with caustics to no avail. From June to September the hair of his scalp, which was always plentiful, had fallen out to such an extent that he was almost completely bald. The areas denuded were perfectly clean, showing no signs of inflammation or broken-off hair stumps. The face was practically free of hair. I referred the patient to another excellent dermatologist, who confirmed the diagnosis of alopecia areata and advised ultraviolet therapy, saying that local measures were of no avail. For some time I have been giving the patient weekly exposures of erythema doses of Alpine light, irradiating scalp, face and trunk. In spite of this, the alopecia is progressing. His eyebrows and eyelashes are now falling out, about half the hair has been lost from the forearms, and areas of alopecia are appearing on the thighs. The pubic and axillary hair are as yet intact. Is any other form of therapy worth trying? There are no foci of infection and the patient is of a very stable nervous temperament. The alopecia did not follow any known event, such as a nervous shock or infectious disease. Kindly give references on this subject.

M.D., New York.

ANSWER.—There is little that is known with certainty about the cause of alopecia areata. The important theories advanced to explain its presence are the infectious, toxic, neuropathic and endocrine.

Syphilis is said to be a cause or associated with the occurrence of alopecia areata by a number of competent observers. Epidemics have been reported from institutions for children. That certain chemicals and toxins are capable of inducing alopecia is shown by the action of thallium. Deviations from the normal activity of the thyroid and sex glands have been seen in association with loss of hair. Injuries to the head or acute anxiety may be causative.

The treatment which the patient received is of the kind usually used. Since the man's basal metabolism is below normal and good results not infrequently follow thyroid feeding, it should be continued. It is quite probable that the patient's alopecia is on an endocrine basis. Besides thyroid activity, investigations of other endocrine glands should be made. Anterior and posterior pituitary substance may be given by injection and by mouth. There is nothing wrong except for the alopecia, so all one can do is to apply empirical measures. Some local irritant and parasiticide may be applied, such as Cutler's fluid. This consists of equal parts of phenol, chloral hydrate and tincture of iodine. It is used once or twice a week, depending on the degree of the irritational response. Ultraviolet baths are an accepted form of treatment. Epilating doses of x-rays have been recommended. It is well to try one small area first to see how useful this measure will be. Mental depression should be combated and the patient's attention should be diverted from himself by engaging him in work or travel. In universal alopecia occurring in adults the prognosis is apt to be bad, but persistence in treatment is necessary if only to keep the patient hopeful.

DIMETHYL SULFATE

To the Editor:—A patient is doing research work and is using dimethyl sulfate. What precautions should he take to prevent any poisoning? What would be the symptoms and treatment in case of poisoning?

GEORGE A. BAKKE, M.D., Oakland, Calif.

ANSWER.—Dimethyl sulfate is one of the most toxic substances used in industry and should be manipulated only by highly skilled and experienced persons. Prosser White (*The Dermatogoses or Occupational Affections of the Skin*, Fourth Edition, H. K. Lewis & Co., Ltd., London, 1934, p. 312) states "Dimethyl sulphate . . . is extremely poisonous and one of the most dangerous substances used in the colour industry. Its vapour has a delayed action which ends in a burn, like that from sulphuric acid." Any person responsible for the guiding of workers handling this material should consult the references appended at the end of this brief comment. In general, it may be stated that dimethyl sulfate may be prepared by distilling a mixture of chlorosulfonic acid and methyl alcohol. The vapors from these substances constitute the chief source of injury, which may be either local or systemic. The local injury is one of an extensive caustic burn, varying from simple redness to extensive ulceration and necrosis. After absorption systemic disease may be manifest by convulsions, coma, paralysis, associated with

marked vascular and renal disturbances. Changes take place in the blood characterized by polycythemia and leukocytosis. The temperature may reach high levels. The eyes are especially prone to injury from local action. By way of prevention and first aid the following is suggested:

Suitable rubber gloves should be worn whenever direct hand contact is possible. If exposure has taken place all clothing quickly should be removed and the body sponged with dilute aqueous ammonia. Immediate showers with water may be preferable. Mild alkaline solution should be utilized for flushing the eyes. Industrial operations should be carried out only in enclosed systems. If vapors are to be discharged from semi-enclosed systems, such discharges should take place from comparatively high stacks so that ample solution may preclude injury to persons in the neighborhood. In work rooms where accidents have arisen leading to prospective discharge of vapors into work rooms, all workmen quickly should leave the dangerous area. Workers suffering from or prone to suffer from inflammatory disorders of the eye or respiratory tract should not be employed for duties involving exposure to dimethyl sulfate. In general, the same degree of respect should be extended to dimethyl sulfate as to mustard gas.

TRICHOMONAS INTESTINALIS

To the Editor:—Please give possible drugs or other therapy for treatment of *Trichomonas intestinalis* infestation. A patient has been treated two weeks with enemas of warm salt solution and copper sulfate with no relief from diarrhea, abdominal pains or gross number of parasites microscopically. Is there any other organism that would be mistaken for *Trichomonas intestinalis*?

M.D., New Mexico.

ANSWER.—It is doubtful whether *Trichomonas* is a true intestinal pathogen, and other etiologic agents such as the dysentery bacillus must be eliminated.

There is no specific treatment for *Trichomonas intestinalis* infestation. Ratcliffe showed that four types of resorcinols when fed to rats which harbored *Trichomonas* in the intestine produced a rapid change in the intestinal flora so that one type of *Trichomonas* (*muris*) disappeared entirely and another type (*parva*) was reduced to 10 per cent of its original number. Ratcliffe also stated that a small number of human infections treated with N-heptyl resorcinols showed excellent results. Castellani recommended methylthionine chloride in 0.12 to 0.18 Gm. capsules three times a day by mouth, and bowel irrigations with from 1:3,000 to 1:5,000 solution.

Escamel considered turpentine almost a specific for intestinal trichomoniasis. He described two forms of therapy in his book "La trichomonosis intestinal." In the one that he prefers, for three days a tablespoonful of the following prescription is taken every two hours: pure oil of turpentine from 2 to 4 Gm., camphorated tincture of opium from 6 to 12 Gm., acacia 120 Gm., syrup of acacia 30 Gm. The diet is restricted to carbohydrates, and liquid ingestion is limited to rice water. In addition, from one to three enemas are given, alternating as follows: first an evacuating injection; second a retention enema consisting of four spoonfuls of boiled water, a beaten egg yolk, 10 drops of tincture of opium and from 15 to 30 drops of oil of turpentine. After three days of treatment the feces are examined. If *Trichomonas* is not found, treatment is stopped and the diet is gradually changed to normal. If *Trichomonas* is found, the treatment is continued until the organisms disappear. For cases that are resistant to turpentine, Escamel recommended compound solution of iodine, one part in 1,000 parts of water as an enema on each of three successive evenings.

Chiniofon has been recommended for *Trichomonas intestinalis* infestation as well as for amebic dysentery. It is given orally in doses from 0.25 to 1 Gm. in the form of pills or cachets three times a day. It is also administered rectally, from 1 to 5 Gm. freshly dissolved in 200 cc. of water at a temperature not above 44 C. This treatment may have to be continued for several weeks. Because of the iodine in chiniofon, care must be exercised in patients with thyroid disturbance.

It is rarely possible to confuse *Trichomonas intestinalis* with other organisms in the intestine.

ESTROGEN IN URINE—NEGATIVE ASCHHEIM-
ZONDEK TEST IN PREGNANCY

To the Editor.—Please give me the details of the urine examination for follicular and follicle-stimulating hormones. I should also like an explanation for the occasional negative Aschheim-Zondek test in a pregnant woman. What is the relationship of the presence of either the follicular or the follicle-stimulating hormones to pregnancy?

E. L. FITZSIMMONS, M.D., Evansville, Ind.

ANSWER.—Estrogen in the urine may be detected by the method of Kurzrok (The Endocrines in Obstetrics and Gynecology, Baltimore, William Wood & Co., 1937). This is a modification of the Allen-Doisy test for the production of estrous changes in castrated rats as evidenced by the production of a vaginal spread containing epithelial cells both nucleated and nonnucleated.

The gonadotropic factor is best detected by means of the Aschheim-Zondek test or the Friedman modification of this test. The latter is most widely used because of the relative simplicity of technic and the fact that using rabbits makes the gross observation of the test more satisfactory. For this purpose a previously segregated female rabbit is injected intravenously with 10 cc. of the suspect urine. The rabbit is examined twenty-four hours after the injection. The abdomen is opened and the ovaries are inspected. If the test is positive, hemorrhagic follicles or corpora lutea or both will be found.

The occasional negative Aschheim-Zondek test as obtained with the urine of a pregnant woman may be due to the presence of an insufficient amount of gonadotropin or to occasional refractoriness of the test animal. In the former case a subsequent test will be positive. One may avoid the latter source of error by retesting every animal that gives a negative test, using urine from a patient who is known to be pregnant. If this urine produces a negative test, the animal is refractory.

Gonadotropic substance makes its appearance in large quantities early in pregnancy and can often be detected within a week or ten days after pregnancy has taken place. It steadily increases in amount until about the fifth month of pregnancy, when it reaches a peak and begins to diminish. The amount of estrogen rises slowly in early pregnancy but continues to increase until term is reached. This explains why tests for detection of gonadotropin are of greater value in the determination of early pregnancy than are tests for estrogen.

CHROME DUST AND LUNG CANCER

To the Editor.—What is the possibility of continuous exposure to chrome dust (sodium dichromate) being the causative factor in carcinoma of the lung? Are there any references to this subject available?

W. H. LONGLEY JR., M.D., Jersey City, N. J.

ANSWER.—Several references are available dealing with lung cancer among chromate workers:

- Teleky, L.: Occupational Cancer of the Lung, *J. Indust. Hyg. & Toxicol.* 19:73 (Feb.) 1937.
Lehmann, K. B.: Ist Grund zu einer besonderen Beunruhigung wegen des Auftretens von Lungenkrebs bei Chromatarbeitern vorhanden? *Zentralbl. f. Gewerbehyg. u. Gewerbehyg.* 9:168 (Aug.-Sept.) 1932.
Pfeil, E.: Lungentumoren als Berufskrankung in Chromatbetrieben, *Deutsche med. Wochenschr.* 61:1197 (July 26) 1935.
Alvens, W.; Bauke, E. E., and Jonas, W.: Auffallende Häufung von Bronchialkrebs bei Arbeitern der chemischen Industrie, *Arch. f. Gewerbehyg. u. Gewerbehyg.* 7:69, 1936; abstr. *München. med. Wochenschr.* 83:485 (March 20) 1936.
Campbell, J. Argyll: Cancer of the Human Lung and Animal Experiment, *J. Indust. Hyg. & Toxicol.* 19:449, 1937.

Teleky, in the paper cited, says: "Inhalation of chromate dust by workers in chromate factories produces a relatively high incidence of this disease [pulmonary cancer] and perhaps also of cancer of the digestive tract."

BACTERIOPHAGE THERAPY

To the Editor.—What is the present status of the so-called bacteriophage treatment of disease? I have in mind especially the use of this preparation in general peritonitis.

M.D., North Carolina.

ANSWER.—d'Herelle, who did most of the early work on bacteriophage, conceived of it as an ultramicroscopic living agent which produces a disease of bacteria ending in "lysis" or disruption of the cell. He believed that the introduction of the proper bacteriophage into the diseased host would result in mass destruction of the invading organisms. As a consequence of d'Herelle's encouraging views, innumerable clinical trials of bacteriophage therapy were undertaken. While many favorable reports followed, particularly in the early phases of clinical experimentations, the consensus of competent opinion now seems to be that bacteriophage therapy has no intrinsic value; i. e., bacteriophage injected into the patient does not effectively bring about bacterial destruction in tissue foci. The reason for this

has been made clear by the studies of Krueger and Northrop and the more recent work of Krueger (see series of papers in the *Journal of General Physiology* from 1929 to 1937) on the mechanism of the bacteriophage-bacterium reaction. The primary difficulty seems to depend on two facts: 1. A certain high ratio of bacteriophage to bacteria is requisite for lysis. 2. The rapid production of bacteriophage requires optimal bacterial growth. Under ordinary conditions in a tissue, bacterial growth is far from optimal and is held in check by various mechanisms of host resistance and therefore little bacteriophage is formed (Krueger, A. P.; Lich, R., Jr., and Schultze, K. R.: *Proc. Soc. Exper. Biol. & Med.* 30:73 [Oct.] 1932) and even that small amount is bound to a considerable extent by tissue colloids. Hence the critical lytic threshold value is seldom attained.

Krueger several years ago advanced proof that bacteriophage is a protein with the properties of an enzyme, and Northrop has recently confirmed this by isolating a protein which possesses all the properties of bacteriophage (*J. Gen. Physiol.* 21:335 [Jan.] 1938). There seems to be no more reason to employ the term living in connection with bacteriophage than there is to use it with reference to an enzyme or a virus such as Stanley's tobacco mosaic virus.

There is no satisfactory proof that bacteriophage is of value in the treatment of peritonitis.

HEMOCHROMATOSIS

To the Editor.—A woman aged 29 with diabetes is beginning to have a definite bronzing of the skin, with hypotension. Her blood pressure ranges from 94/62 to 80/30. She has had one attack of diabetic coma. There is no evidence of cirrhosis of the liver or ascites. Does hemochromatosis ever occur in the female? Is it always accompanied by cirrhosis of the liver and ascites?

T. K. LEWIS, M.D., Birmingham, Ala.

ANSWER.—For the detection of hemosiderin in the urine a method often used is that of Rous (*J. Exper. Med.* 28:645 [Nov.] 1918). It is outlined in Todd and Sanford: *Clinical Diagnosis by Laboratory Methods*, ed. 8, Philadelphia, W. B. Saunders Company, 1935, page 138. In the case cited it would be valuable to examine a section of the skin for iron pigment and excess melanin.

In Sheldon's monograph on hemochromatosis (London, Oxford University Press, 1935) an analysis is made of 311 "genuine" cases reported in the literature. Sixteen of these, or only 5.1 per cent, were in women. Cirrhosis of the liver is an essential feature of hemochromatosis in contrast to diabetes and bronzing of the skin, which may be absent. Ascites often occurs in the later stages of the disease; it was recorded in 22 per cent of Sheldon's series and he believes that the true frequency is much greater.

The most satisfactory way of diagnosing hemochromatosis during life is to excise a bit of skin from an abnormally pigmented region. The full thickness of corium should be included. The skin should be fixed in solution of formaldehyde or in alcohol, sectioned in paraffin, and stained by the technic recommended by Warren (*Pathology of Diabetes Mellitus*, ed. 2, Philadelphia, Lea & Febiger, 1938).

TREATMENT OF TAENIA SAGINATA INFESTATION

To the Editor.—I have as a patient a middle-aged woman infected with *Taenia saginata*. She has at various times taken the usual anthelmintics, including pelletierine and aspidium, without completely eliminating the parasite. Please suggest a satisfactory treatment.

L. MAXWELL LIDE, M.D., Florence, S. C.

ANSWER.—Aspidium has been a drug of choice for the treatment of tapeworm for a number of years. Frequent failures to remove the complete worm with this drug have been reported and are in part due to the method and dosage employed. Magath and Brown have standardized the aspidium treatment for tapeworm and report uniform success. (*THE JOURNAL*, May 14, 1927, p. 1548.)

Carbon tetrachloride was introduced for the treatment of tapeworms by Daubney and Carman (*Parasitology* 20:185 [July] 1928). Owing to the simplicity of the method and its great efficiency, from 70 to 97 per cent of the worms being removed by one treatment, it enjoys wide usage. Treatment for an adult is carried out as follows:

To avoid the possibility of intoxication from carbon tetrachloride the patient should be put on a high calcium diet from ten days to two weeks before treatment, and no meat should be given for a day or so before or after the administration of carbon tetrachloride. A light evening meal should be taken, but a preliminary purge has been found unnecessary. In the morning, breakfast should be omitted and carbon tetrachloride given early.

Thirty Gm. of magnesium sulfate should be dissolved in half a glass of water and the adult dose of 3 cc. of carbon tetrachloride should be shaken up in this solution and swallowed. No breakfast should be allowed until the purge has acted. Following the action of the purge a warm soapsuds enema may be given and the stool examined for the head of the worm. Alcohol should not be taken during treatment.

ALLERGY TO MERCURY IN AMALGAM FILLINGS

To the Editor:—A woman has a skin eruption diagnosed by one skin specialist as "infectious dermatitis" and by another as an allergy against mercury. A skin reaction to mercury can be experimentally produced. She has a great many silver amalgam fillings in her mouth. Has an allergic reaction to the mercury in fillings been reported?

NITA MIETH ARNOLD, M.D., Chicago.

ANSWER.—Allergy to mercury is one of the most common causes of allergic dermatitis. The usual contact is one directly to the skin either by the handling of mercury compounds or by the use of medicaments containing mercury, such as antiseptics and mercury ointments. That sufficient mercury may be absorbed from amalgam fillings to cause mercury poisoning is evidenced by the numerous reports in literature, among which are the following:

Stock, A.: *Arch. f. Gewerbepath. u. Gewerbehyg.* 7: 388, 1936.

Stefensen, K.: *Ugesk. f. læger.* 96: 855 (Aug. 2) 1936.

Herrenknecht, W., and Scheidt, C.: *Fortschr. d. Zahnh.* 6: 664 (Aug.) 1930.

Meyer, E.: *Med. Welt* 4: 703 (May 17) 1930.

Flüchel, A.: *Aertzt. Rundschau* 38: 309 (Oct. 25) 1928.

It stands to reason that, if sufficient mercury can be absorbed from amalgam fillings to produce mercury poisoning, the amount would be sufficient to produce inflammatory reactions of the skin if the patient happened to be sensitive to mercury.

Dermatitis can be produced by injection of mercury salts. A case is reported of dermatitis caused by the mercury in dental amalgam (Blumenthal, Franz, and Jaffé, Käte: *Deutsche med. Wchnschr.* 55: 1720 [Oct. 11] 1929).

There are undoubtedly other cases in the literature and many more unreported. Attention must be called to the fact that other metals also are used in dental fillings, and the possibility of dermatitis due to other metals must be kept in mind.

RIVERS' SMALLPOX VACCINE

To the Editor:—What is Rivers' smallpox vaccine and how is it used?
M.D., New York.

ANSWER.—Rivers' smallpox vaccine is prepared in modified tissue cultures consisting of minced chick embryo tissue suspended in Tyrode's solution. After cultivation, when the material has been shown to be bacteriologically sterile, it is mixed with sterile acacia solution, frozen and desiccated.

When desired for use, an ampule is opened aseptically and sterile water or salt solution is added as a diluent. After the material has been thoroughly mixed in the diluent, 0.1 cc. is given intracutaneously.

Reactions appear usually between the fourth and the tenth day after inoculation; seven days is the average length of time. As a rule no open sore develops and the reaction, which consists of redness and swelling, disappears within three weeks.

Rivers, T. M., and Ward, S. M.: *Jennerian Prophylaxis by Means of Intradermal Injections of Culture Vaccine Virus*, *J. Exper. Med.* 62: 549 (Oct.) 1935.

INJECTION OF PROCAINE HYDROCHLORIDE FOR SPRAINS

To the Editor:—Is it considered good practice to inject procaine hydrochloride into a sprained knee as routine treatment? An osteopath nearby is doing this in order that children may continue to play basketball. I advised taping the sprained knee, with rest.
M.D., Colorado.

ANSWER.—A sprain of any kind indicates injury to supporting tissues. A sprained knee should be protected against reinjury and supported either by a splint or by adhesive strapping and an elastic bandage until the injured tissues have had time to repair. Injection of procaine hydrochloride into a sprained joint, to relieve the pain so that activity may be made possible, is a dangerous procedure. The pain which is present, after such an injury, is nature's way of warning the individual that damage has been done and that further activity producing the pain is increasing the injury. The local anesthetic simply paralyzes the warning signal and is as much a mistake as it would be to disconnect the burglar or fire alarm simply because the sound of it annoyed the owner of the establishment in which it had been installed.

EXCRETION OF BROMIDES

To the Editor:—Bastedo in his "Therapeutics" says that the bromides are slowly eliminated and that for weeks they may be detected in the urine and blood. How long would the effect last? How long would it be until the body would be entirely free from the effect of the bromism? I realize that this is a hard question, but bromides are used so freely in medicine that it must be important to those who use or prescribe them to know what the final result will be on the patient.
M.D., California.

ANSWER.—The kidneys excrete bromide [Br⁻] less efficiently than iodide [I⁻] and chloride [Cl⁻], so that several days may be required to excrete the major portion that is in the body when the administration is stopped.

The rate and duration of excretion and the persistence of the effects depend on the original bromide level. With a single dose of 1 or 2 Gm., little effect remains after twelve to twenty-four hours; but with doses large enough to produce major toxic effects it may take a week till the bromide has fallen to an innocuous level. The excretion may be hastened by administration of sodium chloride. If a bromide acne or other dermatitis has started, this may take a little time to heal after the bromide level has fallen.

Traces of bromide may be detected in the urine for at least three weeks after its administration has been stopped but these quantities are too small to be significant.

FAMILIAL PERIODIC PARALYSIS

To the Editor:—In Queries and Minor Notes in THE JOURNAL, June 11, page 2026, appeared a discussion of familial periodic paralysis in which it was stated that no practicable treatment is available. Through my work dealing with the biochemical and physiologic role of potassium in the animal organism, I am acquainted with the literature of this mineral element. Recently two groups of investigators (Herrington, M. S.: *Successful Treatment of Two Cases of Familial Periodic Paralysis with Potassium Citrate*, THE JOURNAL, April 17, 1937, p. 1339, and Aitkin and his associates, *Clin. Sc.* 3: 47 [No. 1] 1937) have described a lowering of potassium in the blood serum in cases of familial periodic paralysis during the paralytic attacks and found that administration of potassium salts by mouth raises the serum potassium level and abolishes the paralysis.

ELSA ORENT-KEILS, Sc.D., Baltimore.

To the Editor:—Usually the answers published in Queries and Minor Notes are exceptionally authoritative and therefore I am presuming to call attention to a serious omission of information. In THE JOURNAL June 11, page 2026, in reply to a letter from a Massachusetts physician regarding two cases of familial periodic paralysis, the statement is made "There is no treatment known which is effective either in preventing this disease or in shortening its course." Is it possible that your commentator is not aware of the report of Aitken, Allott, Castleden and Walker (*Clin. Sc.* 3: 47 [No. 1] 1937) entitled "Observations on a Case of Familial Periodic Paralysis," in which the rational use of potassium salts is demonstrated? The confirmatory studies reported by Joseph Ferrebce, Dana Atchley and Robert Loeb at the thirtieth annual meeting of the Society for Clinical Investigation at Atlantic City this spring, as well as the more extended reports from the British investigators in the current issue of *Clinical Science*, should be of interest to your consultant. I have been observing an undoubted case of familial periodic paralysis during the last year. Many years ago the patient discovered for himself that rochelle salt in large doses would effectively abort the paralytic attack. Since the patient has been under my care, we have found that potassium chloride is equally effective.

CLARENCE L. ROBBINS, M.D., New Haven, Conn.

"EXCESSIVE LIBIDO IN MAN"

To the Editor:—THE JOURNAL is looked to throughout the country by physicians as a prominent organ for the dissemination of progress in medical sciences. At times a lack of psychophysiological evaluation is displayed in the answers concerning clinical problems. In the issue of June 11 is a query entitled "Excessive Libido in Man." The inquiring physician has presented evidence of overactivity of at least three glands of internal secretion in his patient: the thyroid, the pancreas and the gonads. Considerable authority exists to indicate that these glands are influenced by emotional states. Moreover, the man was said to be "nervous" and "bromides" were recommended in the answer. Yet no mention was made of employing psychiatric investigation and treatment in this problem. To state that, other than cauterization, "no remedy has thus far been found to alleviate the condition" is an injustice to those physicians who have labored for years, often with therapeutic success, to demonstrate that a need for excessive sexual activity is a neurotic condition. Most readers of THE JOURNAL (myself among them) look to Queries and Minor Notes for instruction in keeping abreast with the most advanced knowledge in the science of healing. Recently I saw a man aged 29, a psychopath with hypochondriacal reactions, who complained of pain in the genitals. He had been subjected to numerous urologic instrumentalizations by various doctors until finally orchidectomy was performed! Such practices have no place in a modern medical world and it is a function of THE JOURNAL to exert such guiding influences in maintaining a high standard of medical thinking and treatment as to make therapeutic errors like this rare.

HERMAN SELINSKY, M.D., New York.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, August 6, page 561.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Examinations will be held in all centers where there is a Class A medical school and five or more candidates who wish to write the examination, Sept. 12-14. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An affiliate of the American Board of Surgery. New York, Oct. 21-22. Applications must be filed sixty days prior to examination. Sec., Dr. Paul M. Wood, 745 Fifth Avenue, New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: St. Louis, Nov. 11-12 if the number of candidates warrants it. Applications of Class B candidates should be filed by Sept. 1 and of Class A by Oct. 1. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Written examinations will be held in various parts of the United States, Oct. 17 and Feb. 20. Application for the October examination must be received before Sept. 15 and for the February examination on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada, Nov. 5. Last date for applications is Sept. 5. General examination for all candidates (Groups A and B) will be given in St. Louis, June. Applications must be filed not later than sixty days prior to date of examination. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: New York, Oct. 7, and Washington, D. C., Oct. 8. All applications should be filed immediately and case reports, in duplicate, must be filed not later than sixty days before the date of examination. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Memphis, Tenn., January. Applications for this examination must be filed with the Secretary on or before Oct. 15. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Washington, D. C., Oct. 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Detroit, October 26; Rochester, N. Y., November 13; and Oklahoma City, November 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 28-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, N. J., Sept. 15-18. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

California March Examination

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held at Los Angeles, March 8-10, 1938. The examination covered nine subjects and included ninety questions. An average of 75 per cent was required to pass. Fifty-four candidates were examined, fifty of whom passed and four failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent

Montana April Report

Dr. S. A. Cooney, secretary, Montana State Board of Medical Examiners, reports the written examination held at Helena, April 5-6, 1938. The examination covered ten subjects and included fifty questions. An average of 75 per cent was required to pass. Five candidates were examined, all of whom passed. Eleven physicians were licensed by reciprocity and two physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Georgetown University School of Medicine.....	(1937)		82.4
Rush Medical College.....	(1936)		82.2, 84.5

Book Notices

A Textbook of Ophthalmology. By Sanford R. Gifford, M.A., M.D., F.A.C.S., Professor of Ophthalmology, Northwestern University Medical School, Chicago. Cloth. Price, \$4. Pp. 492, with 259 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

The author's attempt "to compress within the limited space of a volume which may be used by medical students and general practitioners the essential facts of modern ophthalmology" has been well and thoroughly accomplished. The inclusion of slit lamp microscopy, the measurement of the blood pressure in the retinal vessels, special optical appliances for certain conditions, a list of therapeutic agents employed in ophthalmology, and visual standards adopted by the House of Delegates of the American Medical Association demonstrate the effort to make the text entirely abreast of the time. The colored plates are excellent. If any error has been made in the production of this all inclusive little volume, the voice of derogatory criticism might be directed to the inclusion of so many black and white photographs of fundus conditions and more especially to photographs of diseases of the anterior segment of the eye, which are reproduced too poorly to be of value. Perhaps the author will see fit to replace these by photographs in color or better black and white reproductions in a future edition. The usefulness of the volume is enhanced by thirty pages of index.

Die wissenschaftlichen Grundlagen der Beurteilung von Blutalkoholbefunden. Von Dr. Herbert Elbel, Assistent des Instituts für gerichtliche Medizin der Universität Göttingen. Boards. Price, 7.80 marks. Pp. 106, with 28 illustrations. Leipzig: Georg Thieme, 1937.

This booklet presents in concise form a summary of the literature on the subject of the scientific foundation for the interpretation of the alcohol content of the blood. The thoroughness of the author and his right to an opinion can be appreciated when the 545 references to the literature are considered. Some of the important observations and conclusions of the author are as follows: Alcohol is a factor in about 40 per cent of all accidents involving injury or death. In about 10 per cent of traffic accidents a responsible person had at least 0.2 per cent of alcohol in his blood. The definitely drunken person is less of a menace than one who is less "under the influence" of alcohol. In Germany a driver of a car is under the influence of alcohol when, because of indulgence in alcohol to any degree, he has lost some of his ability to drive his car or to pay proper attention to traffic. It is impossible to diagnose alcoholic intoxication for legal purposes from the clinical symptoms alone, and blood alcohol determinations furnish an important link in diagnosis. A Prussian supreme court further states that even small amounts of alcoholic beverages, which may be insufficient to produce noticeable symptoms, may still be sufficient to affect the safety, agility and distinctness of observation of the driver.

The Widmark method of determining alcohol is considered sufficiently accurate for practical purposes, but an error may be introduced by the presence of ether and acetone. It is interesting to note in this connection that simple tests performed in this country on both blood and urine are not appreciably affected by ether or acetone. The formula of Widmark, by which it is possible to calculate the total amount of alcohol in the body at definite times, is of great medicolegal importance. The ratio of grams of alcohol in the body to alcohol in the blood expressed as parts per thousand is found to average 0.55 for women and 0.68 for men, and the figure that is characteristic for the individual depends on the amount of fat in the body. The author's observations of fasting persons indicates a loss of body alcohol of from 5.4 to 8 Gm. an hour in five men and 4 and 4.3 Gm. in two women.

A discussion of the effect of epinephrine on tolerance for alcohol is particularly interesting, since it suggests the explanation for the sobering effect of fright and excitement; namely, that sudden splanchnic vasodilatation causes a diminished circulation of alcohol through the brain tissue.

A most important conclusion is that the psychic effect of alcohol taken in small doses and associated with low blood alcohol concentrations is so definite that there is no minimal, insignificant or irrelevant degree of consumption of alcohol for the safe handling of a motor vehicle. The author feels that

0.10 per cent of alcohol in the blood is unquestionably associated with definite inferiority, so that the alcohol may be the sole or predisposing cause of an accident. Finally, there is no definite quantitative relationship between blood alcohol concentration and degree of influence; judgment of the degree of culpability also depends on a consideration of the circumstances which brought the individual into contact with the law. This statement is unquestionably correct, but it must be mentioned that several American observers have been able to predict the concentration of alcohol in the blood or urine with remarkable accuracy from careful observation of persons who were arrested for being under the influence of alcohol.

Dream Analysis: A Practical Handbook in Psychoanalysis. By Ella Freeman Sharpe. Cloth. Price, \$2.50. Pp. 211. New York: W. W. Norton & Company, Inc., [n. d.].

Since an understanding of psychoanalysis is highly dependent on the analysis of dreams, one should be able to get a great deal of information from a systematized volume on this subject. The author delivered the material included in this volume in lecture form during the years 1934 and 1936 at the London Institute of Psychoanalysis. It is a well organized volume, not particularly technical or deep, but it does require some knowledge of psychoanalysis to get the most out of it. The author begins the volume with a discussion of a dream as a typical and individual psychic product. There is some discussion here of individual dreams, but the symbolism of these dreams is perhaps too lightly touched on, although later in the book this symbolism is developed to a greater extent. Since it is necessary to understand the mechanisms of dream formation, the author devotes the second chapter to this subject and then goes on to a discussion of the value of dreams to the analyst who obtains a clue to the wish fulfillment from the latent content of the dream. Since not all dreams are the same, various types of dreams are taken up, examples being given, such as a dream related by a man experiencing anxiety with regard to women. The next chapter shows in rather brief and sketchy form how a single dream might be analyzed and studied. The relationship of the dream to the content of the psychoanalyst is not explained in full here and, while one can see from this chapter that a great deal can be accomplished with a dream analysis, one does not see the total picture. Dream analysis of course is not a simple technic, so that it is necessary for the author to discuss problems which have come to her in her experience with dream analysis. She also illustrates dreams which occurred during psychic and physical crises. Psychoanalysis, after all, is aimed at readjustment, and the eighth, ninth and tenth chapters deal with readjustment and the results of analysis of persons with regard to their dreams. There is an appendix giving a list of dreams which were recounted in the book and, while a bibliography is listed in the table of contents, in the volume which was sent for review the bibliography was omitted. All in all this book is somewhat useful in rounding out the literature on psychoanalysis. It does not enable the untrained psychiatrist to do much more with dream material than he could before he read the book; but since opinions, particularly those of experienced people, are needed to polish up psychoanalytic thought, there seems to be a definite place for this volume in the library of the psychiatrist who wishes another point of view on psychoanalysis.

Le phénomène de la guérison dans les maladies infectieuses. Par F. d'Hérelle. Paper. Price, 75 francs. Pp. 414, with 19 illustrations. Paris: Masson & Cie, 1938.

The author has already published two monographs on bacteriology. As he indicates, the present work differs in that it is of more general interest than might be inferred from the title, "Phenomenon of Cure in Infectious Diseases." Bacteriophage has made great progress in the course of the last decade. New proofs which are irrefutable have been discovered, and the facts are now generally accepted even by those scientists who formerly disagreed with the principles involved. d'Hérelle devoted more than twenty years of his life to this study, he made many voyages to all parts of the world, and he has followed epizootics in Cochin China, scourges of cholera in the Indian hospitals and the villages of the Punjab, and epidemics of plague in Asia and Africa. He utilized and improved field laboratories in many cases and studied in this way a multitude

of cases of illness while he lived in the midst of the epidemic. The result of his experience is the advancement of a theory which explains the processes involved in the cure of infectious diseases and the manner in which epidemics are extinguished. In his preface d'Hérelle says "If the theory of cure as advanced and as suggested to me is a true result of my observations, we should be able to reproduce experimentally at will the natural process of cure." The researches which have been made on this subject he relates in the fifth chapter of the work.

This book will interest the bacteriologist and perhaps to a greater degree the biologist in its early chapters, which deal with the actual question of bacteriophage and the problem of bacterial mutations. The portion which deals with the study of infectious diseases and epidemics will present matter of lively interest to the pathologist and the hygienist. For the physician there will be found for each of the diseases actually amenable to this mode of treatment a detailed therapeutic method by *bacteriophage provoquée*, which represents the specific therapy which will tend to provoke in the case of the diseased individual the actual phenomenon of cure. It is impossible, within the limits of this review, to list the many matters of interest which are taken up in this detailed and remarkable work. Outside the matters which have been indicated thus far and which will be found of great specific interest are the studies of cholera, plague, typhoid and paratyphoid fever, staphylococcal infections and anthrax. As no translation exists, the book will have to be read in the original.

A Critical Investigation of the Blood Groups and Their Medico-Legal Application. By Dawood Matta, M.B., Ch.B., Ph.D., Lecturer of Forensic Medicine, The Faculty of Medicine, University of Egypt, Cairo. The Egyptian University Faculty of Medicine, Publication No. 11. Submitted in thesis form to the University of Glasgow, October, 1936. Paper. Pp. 231, with 4 illustrations. Cairo, 1937.

The book is divided into six sections. The results of the original investigations of the author are thoroughly presented in addition to a brief and critical review of the present day knowledge of blood groups. Matta's investigations extended into many phases of the subject. After a study of the subgroups A_1 and A_2 and of the agglutinins α_1 and α_2 he aligns himself with those who hold that the differences between the two are merely quantitative. A titration of 200 specimens of blood group B leads him to the conclusion that as in blood group A there are similar quantitative differences in group B, which he divides into subgroups B_1 and B_2 with the corresponding agglutinins β_1 and β_2 . Further evidence is offered by Matta in support of Schiff's concept of the O factor as a blood group specific antigen and not a species antigen. Interesting and thought provoking is Matta's hypothesis of new genotypic formulas which are based on the assumption that the genotype of each person is composed of four genes that may represent each of the agglutinogens A, B or O. Four of each may be present, or any combination of them. He postulates the existence of fifteen subgroups, four within the groups A and B and six within the group AB. No subgroups are present in group O. The agglutinogens A, B and O are all dominant. Two genes out of the four of each parent are transmitted to the child. The subgroups A_1 and A_2 , B_1 and B_2 are an expression of the quantity of each agglutinin in the genotype. A_1 has the formulas AAAA, AAAO or AAOO and A_2 has the formula AOOO. Similar structural formulas are suggested for the subgroups of B. Matta offers rather convincing arguments in favor of his hypothesis. If it stands the test of time, it would offer a satisfactory explanation for those exceptions from the hypothesis of Bernstein in which illegitimacy could not be invoked. The new hypothesis claims to invalidate that part of Bernstein's hypothesis which denies the possibility of an O child of an AB parent; it also claims to invalidate Thomsen's hypothesis of the inheritance of subgroups A_1 and A_2 . Matta is fully aware that his hypothesis, being based on a small material (ninety-nine families), needs further confirmation. The monograph includes studies on identification of blood groups in stains made by blood and by seminal fluid, and in saliva, with a valuable emphasis on sources of error. The bibliography is rather brief but well selected. The book is indispensable for those interested in the theory of blood groups and in their practical applications, particularly in medical jurisprudence.

Milestones in Medicine: Laity Lectures of the New York Academy of Medicine. Introduction by James Alexander Miller, M.D., President, New York Academy of Medicine. Cloth. Price, \$2. Pp. 276, with illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1938.

This is the second volume of lectures delivered at the New York Academy of Medicine intended to give the layman some idea of background of medicine. As in all symposiums, the various lectures are unequal in their ability to hold the reader's interest. The arrangement of the volume is not such that the average reader would be immediately attracted to its contents. The essays devoted to the history of leprosy, by Newton E. Wayson, and the glands of internal secretion, by Walter Timme, should be, to the nonmedical reader, the most interesting in the volume. One cannot neglect, however, the essays on medicine at sea in the days of sail, by Karl Vogel, and the evolution of the human brain, by Frederick Tilney, which are excellent reading and demonstrate a historical perspective. The chapters on leprosy and medicine at sea are distinctly historical. They deal more with the beginnings of medicine, old customs and beliefs than do the other chapters, while the essay on the evolution of the human brain also contains a great deal that is historical. Timme, in his story of the glands of internal secretion, goes extensively into the stories of research and into the working of the various glands, and occasionally he interjects a sidelight on medical discoveries. There are three other chapters included in this book which are well written by experts, but they do not have the direct bearing on the history of medicine of those previously mentioned. The first chapter, for instance, is by Smith Ely Jelliffe, on the historical background of psychiatry. Ordinarily anything written by Jelliffe should be considered a valuable introduction to any volume in which it is contained. Jelliffe, in his writings and speeches, has always shown a true cultural background, excellent diction and a fascinating way of expressing himself. The present essay shows the first two traits as not particularly interesting—the discourse wanders about, does not cite interesting historical facts in psychiatry and is not up to Jelliffe's standards. The essay on the mechanisms of heredity, by Stockard, is the usual discussion of that subject. Little in the history of medicine is expounded—a few names are mentioned, but not in sufficient fashion to make this other than an essay on a technical medical subject. Dr. Sigerist has included a paper on the history of medical history. In a competent way he points out the various types of historical research which can be found in this field. It is adequate but rather dull. Nevertheless it has a place in the volume because, if one wishes to see the types of study which the other authors who have contributed to the volume have used, they can be interpreted in the light of Sigerist's study.

Handbuch der Erbkrankheiten. Herausgegeben von Dr. med. Arthur Gütt, Leiter der Abteilung Volksgesundheit im Reichs- und Preussischen Ministerium des innern Präsident des Preussischen Landesgesundheitsrats. Band 1: Der Schwachsinn. Von Dr. med. F. Dubitscher. Paper. Price, 24 marks. Pp. 358, with 45 illustrations. Leipzig: Georg Thieme, 1937.

Because of economic and political changes in Germany there have been few studies following the type of monographic material which has previously been made available for American physicians. Before the war we were deluged with ponderous tomes which, if they made difficult reading, contained encyclopedic information. They were what they pretended to be. The present volume is intended to be a description of feeble-mindedness from the standpoint of hereditary diseases with particular reference to the new made tendencies in Germany for sterilization, race purification and the use of medicine for building up the nation as a whole. The volume turns out to be a book which would stress the race purification angle and is a rather heavy study of feeble-mindedness from all angles. About one fourth of the book is taken up with the organic brain changes of the feeble-minded, particularly those due to bacterial or mechanical traumatism. Exotic diseases are discussed in more detail than their frequency deserves. The last fourth of the book is devoted to a mass of intelligence testing material which has not, apparently, been standardized and is evaluated on an objective basis. It is, however, comprehensive. The discussion of sterilization and the German law regarding the sterilization of the feeble-minded is interesting, as it reveals something which American medicine has not heard; namely,

that sterilization has not been entirely enforceable and that while several German race hygienists, foremost among whom is Gütt, who writes the introduction for the present volume, have been trying to do much more sterilizing, the scientific justification of the need for sterilization has not yet been forthcoming, particularly in such cases as mongolian idiocy and those cases which are due to trauma of various sorts. There is a bibliography in this book but it does not compare with bibliographies in earlier handbooks of similar nature. It is incomplete, for much important English literature is omitted although there is a pretense that the English monographs on the subject have been covered. References to individual studies have been made in the text in such a manner that none of the statements can be verified. It scarcely seems necessary to read the present volume to get any new light on the study of feeble-mindedness. We in America seem to be far advanced over the Germans in dealing with the backward and the high grade individual. There is, of course, much valuable material which can be culled from this volume, but the effort involved is probably greater than the value to be received. The chapters on the sterilization law and on purification of the race are interesting to those who would like to know what is going on in Germany with regard to these matters.

Alfred Owre: Dentistry's Militant Educator. By Netta W. Wilson. Cloth. Price, \$4. Pp. 331, with 8 illustrations. Minneapolis: University of Minnesota Press; London: Oxford University Press, 1937.

This volume is the result of a desire of a number of Dean Owre's friends and former faculty associates in the University of Minnesota to sponsor a tribute to his memory. The book sets forth the record and achievements of Dean Owre in an understanding manner and in a completely sympathetic vein. To this extent the volume accomplishes the purposes for which it was written and consequently will be pleasing to his friends and to those who were in accord with his views on the "level technician plan" of dental education and who agreed with Dean Owre's enthusiasm for the Russian communistic system of health service. In a sympathetic, fictional biography, to be read with the full understanding that the reader is perusing it for inspiration, pastime or amusement, it is of no consequence if the presentation departs somewhat from reality. However, the nature of the sponsorship of this book, the fact that it is published by a university press, and the note of authenticity lent to the work by the personnel mentioned in the section on acknowledgments all give the impression that the contents of the volume may be accepted as strictly factual. The importance of any biographic work must be based on the accuracy and truthfulness of its contents. Only thus can history of value be written. It is to be regretted that Miss Wilson's book contains many gross inaccuracies. It is of relatively small import that she undoubtedly wrote with every intention of recording only an accurate history. Unfortunately the fact remains that the volume, in years to come, may be accepted as a true record of an important phase in the history of the dental profession. Any suspicion of deliberate intent to misstate or mislead may be dismissed because of the gross nature of some of the errors. As a tribute of loyal friends, and as a running history of the life and activities of the dean of two dental schools, the book is interesting and well written. However, as a factual history of a controversial period in the growth of the dental profession and its system of education, and as a reference work for the future student of the period, the book, through its loose treatment of important events and conditions, is of little value.

Mental Hygiene for Nurses. By Elizabeth Lee Vincent, Ph.D., Psychologist, Merrill-Palmer School, Detroit, Michigan. Cloth. Price, \$2. Pp. 263. Philadelphia & London: W. B. Saunders Company, 1938.

This little volume is not a brief textbook in psychiatry for nurses but rather a popular presentation of how to make a mental adjustment, which is particularly necessary for members of the nursing profession. There is little discussion of mental disease in it but rather a superficial treatment of emotional adjustment, in a clearcut, highly simplified, fashion. There is nothing that could not be obtained from one of the more thoroughgoing and better developed books on mental hygiene. However, some chapters view specific types of patients, such as obstetric cases, crippled children, the schizophrenic, unmarried mothers, and others from the point of view of the nurse who

wishes to help. There are many types of patient discussed in these chapters but none are given more than a brief paragraph, so that the information which the nurse can use is slight. Between the first chapter and these chapters, which are late in the book, there are general discussions dealing chiefly with methods of building up pleasant and better adjusted personalities for nurses. The information given here is not presented in a manner that is well adapted for the professional person who is able to go through a nurses' training school. It is more for the layman who wishes to overcome timidity and fears and to develop his memory. Background material in the sense of experiment and case records which would enable the professional person to understand both himself and the patient better is largely neglected. There is one chapter that might be commended and that is the chapter on learning. Psychologists, and the author is a psychologist and not a psychiatrist, have stressed learning procedures. Such features of learning as plateaus, laws of learning, are briefly discussed here, and it may be possible that this chapter would aid some nurse in becoming a slightly better student. A well trained mental hygienist or a nurse who is trained in psychiatric nursing under a good staff of teachers would be able to impress her students adequately without this book. The nurse who desires a good mental hygiene background would have to go to one of the more thoroughly developed textbooks in the field to understand the patient and would undoubtedly gain more from experience particularly with psychiatric guidance than she could possibly gain from reading the brief paragraphs in the present volume. One questions whether the author of this book is really acquainted with the problems that confront the nurse in actual practice.

A Biological Approach to the Problem of Abnormal Behavior. By Milton Haytington, M.D., Psychiatrist, Institution for Male Defective Delinquents, Napanoch, N. Y. Cloth. Price, \$4. Pp. 459. Lancaster, Pa.: Science Press Printing Company, 1938.

The writer of this volume is known for his critical attitude toward freudian psychology and the present volume is an attempt on his part to establish mechanistic rather than animistic theories as to the function of the human mind. This is the first volume of a projected two volume analysis of the mind based on its physiologic mechanism. The present volume, with the exception of a few introductory chapters, is divided into two major parts, one dealing with psychophysiology and the other with psychopathology. The general physiologic idea behind the work is based on simple stimulus response or elaborated reflex action. There is not much stress on the pavlovian idea in general but rather gross teachings of the animal psychologists are carried over fairly uncritically so that stress is laid on the sensory mechanism aroused by the stimuli and the form of the response. One relatively new point of view which the writer has added but about which he has given no particular structural demonstration is the concept of anticipation, wherein he indicates that the individual can anticipate certain types of needs, results and procedures in order to attain a significant goal. The second part of the volume, dealing with psychopathology, harks back to the early part of the present century. Much disturbance of various physiologic mechanisms previously described is discussed in order to show how pathologic change occurs. He points out that there are five different methods of making an adjustment: accomplishment, withdrawal, modification of thought, modification of posture, disabling of the machine. Psychopathology is a disturbance of one of these types of adjustment. Although there is no question that the mechanistic point of view of psychopathology is coming more and more strongly to the fore, it seems questionable whether the present volume will be satisfactory. First of all there is little actual demonstration either from the literature or by demonstration as to the validity of the theories on which the discussion is based. True, many of the statements made in the volume which support the author's belief are considered axiomatic, but even such a theory as the synoptic basis of memory has had some grave doubts cast on it in recent years. The present volume emphasizes a possible mechanical basis of thought and seems to be regression to the concepts of psychology which were emphasized by the behaviorist. As the author himself points out, these have not, at least in the strictly mechanical sense, satisfied our needs in the diagnosis and therapeutics of mental disease.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Use of Title "Doctor" by Chiropractor Unlawful.—The defendant, a licensed chiropractor, was convicted of violating a provision of the Wisconsin medical practice act restricting the use of the title "doctor" to persons licensed to practice medicine and surgery, osteopathy, or osteopathy and surgery. He appealed to the Supreme Court of Wisconsin.

The section of the medical practice act under which the defendant was convicted provides:

No person not possessing a license to practice medicine and surgery, osteopathy, or osteopathy and surgery, under section 147.17, shall use or assume the title "doctor" or append to his name the words or letters "doctor," "Dr.," "specialist," "M.D." "D.O." or any other title, letters or designation which represents or may tend to represent him as a doctor in any branch of treating the sick.

It was stipulated that the defendant had advertised and announced himself as "Dr. H. J. Michaels, Chiropractor," or "H. J. Michaels, Doctor of Chiropractic"; that he was a licensed chiropractor under the laws of Wisconsin; that he held a diploma from a chiropractic college declaring him to be a doctor of chiropractic; that he had announced himself as aforesaid on signs about his office and that he had so advertised in pamphlets and newspapers; and that he treated patients by chiropractic adjustments only and fully informed each patient of the method of treatment before giving such adjustments. He contended that under the stipulated facts he had committed no offense under the medical practice act and further that the restriction in that act relating to the use of the title "doctor" was unconstitutional and void. In *Corsten v. Industrial Comm.* (Wis.), 207 Wis. 147, 240 N. W. 834, the court had under consideration the right of a chiropractor to receive compensation for treatment pursuant to the provisions of the workmen's compensation act. The court said in that case:

Under chapter 147 a chiropractor is not a physician, even though he does treat the sick and treat diseases and diagnose. Under that chapter physicians are licensed to practice medicine, section 147.17; while chiropractors receive "a certificate of registration in the basic sciences and a license to practice chiropractic," section 147.23. But "no certificate of registration shall be considered equivalent to a license (to practice medicine)." Section 147.17. And "no person not possessing a license to practice medicine and surgery, osteopathy, or osteopathy and surgery, under section 147.17, shall use or assume the title "doctor" or append to his name the words or letters "doctor," "Dr.," "specialist," "M.D." or "D.O." Section 147.14 (3). Thus these names and letters may be applied only to those who are licensed as physicians to practice medicine and surgery, and conversely those to whom the names and letters may not be applied are not physicians.

Considering the construction thus placed on the restrictions contained in the medical practice act, the court in the present case said, the stipulated facts show that the defendant was clearly guilty of violating those restrictions.

From a consideration of the various acts of the legislature, it was apparent to the court that for more than fifty years the use of the term "doctor" has been restricted in Wisconsin and the right to the use of the term has become associated with those entitled to practice medicine, surgery or, since 1903, osteopathy. The evident purpose of the restriction is to prevent imposition on the general public by the unauthorized use of the term. The defendant claimed that because the degree of doctor of chiropractic had been conferred on him by some school in Indiana, he was entitled to use that term in Wisconsin because it merely represented a statement of fact. When the defendant came to Wisconsin to practice, the court pointed out, he became subject to all the laws of Wisconsin, which certainly could not be modified by a diploma granted by a school in another state. The law providing for the licensing of chiropractors was enacted in 1925 and at the same time the section in the medical practice act relating to the use of the title "doctor" was rewritten and revised. This revision, the court said, was to make it clear that those practicing chiropractic could not hold themselves out as a doctor or append to their names the title of doctor because

that would tend to represent them as doctors authorized to practice medicine, surgery or osteopathy. The situation is not aided, the court pointed out, because the defendant explained to his patients the nature of his treatment before administering it. The title does not aid the defendant in the treatment; it merely aids him in securing the confidence of prospective patients and in inducing people to apply for treatment. The repeated attempts by chiropractors to have the section in question amended by legislative action indicated to the court quite conclusively that the meaning of the section was well understood. To the court the section seemed clear and unambiguous and in no way impaired the constitutional rights of the defendant. The judgment of conviction was therefore affirmed.—*State v. Michaels* (Wis.), 277 N. W. 157.

Malpractice: Self-Inflicted Injury While Anesthetized; Res Ipsa Loquitur.—After an appendectomy, performed by the defendant, the patient was removed to his hospital room and left in charge of a special nurse. When the patient regained consciousness, it was discovered that his left eye had been cut. Subsequently the patient lost his eye and sued the defendant, alleging that the injury was due to the defendant's failure to care and protect him properly during the time he was under anesthesia. The trial court directed a verdict for the physician, and the patient appealed to the court of appeals of Tennessee, eastern section.

An ophthalmologist testified that the plaintiff's eye had been cut by a sharp instrument, probably by a finger nail, and that the injury was probably self inflicted. The plaintiff apparently argued that the physician was liable by reason of the doctrine of *res ipsa loquitur*. That doctrine, said the court, asserts that whenever a thing which produces an injury is shown to have been under the control and management of the defendant, and the occurrence is such as in the ordinary course of events does not happen if due care has been exercised, the injury will be deemed to be due to the defendant's negligence, in the absence of any explanation by the defendant tending to show that the injury was not due to his want of care. While the doctrine has no application to the ordinary malpractice case, it should be applied, the court said, when a sound and unaffected member of the body, not the subject of the physician's diagnosis or treatment, is injured or destroyed while the patient is unconscious and under the immediate and exclusive control of the physician. The physician argued, apparently, that the doctrine should not be here applied because the injury was not shown to have resulted from the use of an "instrumentality" under his management and control. But, said the court, a human body, freed of the control of a conscious and rational mind, becomes an "instrumentality" potentially dangerous.

The patient contended that, within the meaning of the doctrine, he remained under the control of the defendant from the administration of the anesthetic until he regained consciousness the following morning. While the patient, said the court, remained under the control of the physician so long as he was in the operating room, after he was removed to his private room and after the physician left that room he was under the control of the graduate nurse. It was not shown, the court said, that the nursing of the patient, following the operation, was any part of the undertaking of the physician. During the performance of an operation a hospital nurse, although not in the regular employ of the operating physician, is under his special supervision and control and during that time the relation of master and servant, or principal and agent, exists and the physician is responsible for the negligence of the nurse. But, in the absence of special contract, the physician is not responsible for a negligent act of a nurse in the after-treatment of the patient following the operation unless it appears that the physician assumes to continue his control and direction of the nurse following the operation. The burden of proof rested on the patient to establish as a prerequisite to the application of the doctrine of *res ipsa loquitur* that the injury occurred while the plaintiff was under the control of the defendant. This the patient failed to do.

The physician did not assume responsibility for the safety of the patient following the operation because of a remark he made to members of the patient's family, after the patient had been taken from the operating room to his private room and on

being informed that the patient was violent under ether, to the effect that "we" will take care of him. The physician merely intended to reassure the family that the patient would be properly cared for at the hospital. In leaving his patient in charge of the graduate nurse the physician was guilty of no negligence. The evidence showed that graduate nurses are especially trained to care for patients following operations of this kind; that most patients are violent to some degree while under anesthesia; that it is considered safe practice to leave patients in the care of a graduate nurse, following the administration of an anesthetic; and that it was not customary for physicians to remain with their patients until they recover consciousness.

The court of appeals concluded, therefore, that the trial court was correct in directing a verdict for the physician.—*Meadows v. Patterson (Tenn.)*, 109 S. W. (2d) 417.

Malpractice: Radium Treatment of Facial Blemish Allegedly Resulting in Burns.—In 1922 the plaintiff, when 4 years old, developed on her forehead a pinkish area which was diagnosed by a physician as a birthmark. She was taken to the defendant physician, a dermatologist, who attempted to remove the blemish with radium. Following the second treatment, which according to the plaintiff's evidence occurred two weeks after the first treatment, the part of the plaintiff's forehead to which the radium had been applied assumed a burned or seared appearance, with a cracking and discoloration of the skin. The condition grew progressively worse and seriously affected the skin and the underlying bone structure in a manner plainly discernible. Attributing the resultant condition to the defendant's negligence in applying the radium treatment, the plaintiff sued. At the close of the plaintiff's case the trial court, on motion of counsel for the defendant, withdrew the case from the jury and gave judgment for the defendant. The court of appeals, Ohio, affirmed that judgment and the plaintiff appealed to the Supreme Court of Ohio.

A motion for a directed verdict, said the court, accepts as true every fact offered in evidence by the plaintiff with the reasonable inferences deducible therefrom. The defendant, called for cross examination, admitted it would be "inadvisable" to give treatments of the kind to which the plaintiff had been subjected oftener than three weeks apart and asserted that in the plaintiff's case three months should have intervened between treatments. He maintained, however, that a period of three months did actually transpire between the first and second treatment, and that the affliction concerning which the plaintiff complained was not due to a burn but to a disease known as scleroderma. On the other hand, the plaintiff's father and grandmother testified positively that a space of but two weeks elapsed between the first and the second radium treatment. Two dermatologists took the stand as plaintiff's witnesses but on cross examination they testified that their present opinion was that the plaintiff's blemished forehead was the result of scleroderma and not of a burn. Another medical witness for the plaintiff testified that in his opinion the condition of the forehead was due to a radium burn, "the second treatment being given too near the first treatment; there was evidently an accumulative condition in her case after the first treatment of radium, and the burn resulted." This witness could discover no indication of scleroderma. At the instance of the trial judge, and by agreement of counsel, a professor of pathology in the medical school of Western Reserve University became a witness. "In my opinion," said this witness, "that is not a radium burn, and is more like a scleroderma than any other disease I know." On examination by counsel for the plaintiff, this witness admitted there was some evidence of a radium burn, and that a previous written report in the matter, prepared by his assistant, contained a diagnosis of cutaneous cicatrix or skin scar. Viewing the plaintiff's evidence in the light most favorable to her claim, she presented, in the opinion of the court, a chain of circumstances and events from which the ultimate facts of negligence and proximate cause could be reasonably inferred. The plaintiff having thus made a prima facie case, it was reversible error for the trial court to take the case from the jury and render judgment for the defendant.

The trial court did not err in declining to permit counsel for the plaintiff to interrogate the two dermatologists, who testified for the plaintiff, regarding the opinion held by them as to the

cause of the plaintiff's affected forehead at a time prior to their advent as witnesses at the trial. These physicians, the court said, took the stand as plaintiff's witnesses, and the record suggests that counsel for the plaintiff had been advised by them before they were called that their ultimate opinion was unfavorable to the plaintiff's contention. Medical experts, said the court, should state the opinions they hold at the time they testify, rather than the opinions held at some previous time.

The judgments of the trial court and of the intermediate appellate court were reversed and the cause remanded to the trial court for further proceedings.—*Hubach v. Cole (Ohio)*, 12 N. E. (2d) 283.

Libel: Imputation of Tuberculosis Not Actionable Per Se.—A newspaper item, in discussing the situation at a state tuberculosis sanatorium, contained a statement that "there are a number of persons employed there, including part-time doctors, who are so-called arrested cases of tuberculosis." There were four part-time physicians employed at the sanatorium and one of them, the plaintiff in this case, instituted an action for libel against the newspaper. The trial court sustained a demurrer interposed by the defendant and the plaintiff appealed to the Supreme Court of Wisconsin.

The newspaper item, said the Supreme Court, did not refer specifically to the plaintiff by name nor did it state that all of the part-time physicians had tuberculosis. The plaintiff, therefore, was not, in the opinion of the court, sufficiently identified to entitle him to sue. Furthermore, to charge that a person has an arrested case of tuberculosis is not actionable per se; special damages must be alleged and proved. The complaint in this case alleged no special damages and for that reason the trial court committed no error in sustaining the demurrer.—*Kassowitz v. Sentinel Co. (Wis.)* 277 N. W. 177.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Am. J. Syphilis, Gonorrhea and Ven. Dis., St. Louis

22: 401-536 (July) 1938

- *Infectiousness of Semen of Patients with Late Syphilis: Experimental Study. J. E. Kemp, Chicago.—p. 401.
- Serologic Reactions and Immunity in Relation to Infection and Treatment of Syphilis. J. A. Kolmer, Philadelphia.—p. 426.
- *Appraisal of Laughlen Serologic Test for Syphilis. G. S. Usher, Baltimore.—p. 452.
- Method for Quantitation of Inoculums in Experimental Syphilis. H. J. Morgan and G. P. Vryonis, Nashville, Tenn.—p. 462.
- Further Experiences with Mapharsen; Its Use in Latent Syphilis. G. D. Astrachan and F. Wise, New York.—p. 470.
- Experimental Contribution to Study of Antisyphilitic Hyperthermy Produced by Physical Agents. A. Bessemans, Ghent, Belgium.—p. 478.
- Role of Biopsy in Diagnosis of Venereal Diseases: Histologic Differentiation of Venereal Granuloma and Lymphogranuloma and Chancroid. E. R. Pund, R. B. Greenblatt and Georgia Brawner Huie, Augusta, Ga.—p. 495.
- Spirochetes in the Brain in General Paresis in Jamaica. G. M. Saunders, Kingston, Jamaica, British West Indies.—p. 503.
- Syphilis in Dependent Mothers. Helen Harrington and L. J. Matschat, New York.—p. 513.

Semen of Patients with Late Syphilis.—In an experimental study of the infectiousness of the semen in late syphilis, Kemp inoculated rabbits intratesticularly with fifteen specimens of semen from fifteen different persons, all with syphilis of a duration of four years or more. In an attempt to evaluate the experimental methods of Kertesz, five of the fifteen specimens of semen were collected aseptically and portions of each were inoculated into the posterior chamber of one eye of each of the two rabbits which received the intratesticular inoculation. The control groups comprised rabbits inoculated in the posterior chamber with the semen collected aseptically from four nonsyphilitic persons and rabbits inoculated in the same manner with material collected under cleanly but not aseptic conditions from four nonsyphilitic persons. Except that the ophthalmia acquired by the animals inoculated with the semen that was not collected aseptically was somewhat more severe, there was little difference in the appearance of the eyes of the animals inoculated with the semen of syphilitic and nonsyphilitic individuals. The contentions of Kertesz that inoculation of the posterior chamber of the eye is to be preferred to other methods of inoculation were not confirmed. A review of the available literature shows that, including the present fifteen cases, the semen of 144 persons with syphilis has been investigated for the presence of spirochetes. Sixty-seven persons had early syphilis (syphilis of four years or less) and fifty-two had syphilis longer than four years. Spirochetes were demonstrated in the semen of thirteen of the former group. The majority of this group had untreated florid secondary syphilis or infectious mucocutaneous relapses. In contrast, in only one instance were spirochetes demonstrated in the semen of the fifty-two persons with late syphilis. Because of insufficient data, it was not possible to determine accurately the influence of treatment on the presence of the spirochetes in the semen of the fifty-two patients with late syphilis. Of the fifteen patients in the author's group about whom this information was available, approximately one half were untreated. The semen of all fifteen was noninfectious for rabbits.

The Laughlen Test for Syphilis.—Usher states that the Laughlen test gave an excessive number of positive reactions on 181 presumably nonsyphilitic persons. When the sensitivity

of the reagent was reduced sufficiently to eliminate these falsely positive reactions, it failed in a significant number of instances to detect reagin in serums which were positive to the Eagle flocculation reaction. It is concluded that the Laughlen serologic test for syphilis may be of value in a reliable laboratory as a spot or exclusion test but is not a satisfactory test to be used by a "medical practitioner or technician without special training" (as claimed by Laughlen).

- *Effect of Direct Application of Cod Liver Oil on Healing of Ulcers of the Feet in Patients with Diabetes Mellitus. H. Brandaleone, New York.—p. 141.

Treatment of Peptic Ulcer.—Cutler points out that since Peck's report (medical treatment of peptic ulcer), that is from 1924 through 1937, 262 patients have been operated on at the Roosevelt Hospital (269 operations) for chronic ulcers of the stomach and duodenum, exclusive of operations for acute perforations of primary ulcers. It is of interest to observe that year by year the number of operations performed for these conditions has gradually diminished, and this without a significant diminution of the number of cases admitted. In 1926 there were forty-six such operations, in 1936 but twelve. This change has been due primarily to the increasing recognition of the fact that careful medical management is capable of relieving or controlling a considerable number of these cases. Surgery is indicated only in cases in which the medical regimen has failed or in which complications have resulted. All cases of chronic peptic ulcer are now considered as medical problems primarily and the patients are admitted directly to the medical wards. Not only is no patient now operated on at the Roosevelt Hospital for chronic peptic ulcer without having had a thorough, controlled and efficient course of medical management; but each patient for whom operation is proposed must be passed on by a "court" consisting of physician, surgeon, gastro-enterologist and roentgenologist. The type of operation to be employed in each case is determined by certain guiding principles: 1. The operation must be of such a nature that the particular patient can tolerate and survive it. 2. Not only should it aim at alleviation of symptoms, but it should give freedom from likelihood of recurrence or of complications, both early and late. 3. The ideal procedure having been determined, it should be abandoned or modified if the condition found at operation warrants. The pursuit of the foregoing policies and practices is encouraged by the early results in the present group of cases. The fourteen year period covered by the report shows a mortality in Polya and Billroth II resections, for all types of primary peptic ulcer, of 9.3 per cent. This compares favorably with the 8.5 per cent mortality of gastro-enterostomies during the same period, when one considers the 16 per cent of recorded late poor results with gastro-enterostomy, as against the 3 per cent of poor results with resection. These figures do not take into account the cases of secondary complications.

Cod Liver Oil and Ulcers of Feet.—Brandaleone observed two groups of diabetic patients; one a control group of eleven patients who received routine foot care (article on procedure abstracted in *THE JOURNAL* Feb. 27, 1937, page 760) and group 2, consisting of twenty-one patients who had received

cally to both *Bacillus pertussis* and *Bacillus bronchisepticus*, these cultures are identical with neither. Their significance in connection with whooping cough is not yet clear. For convenience of reference, the name *Bacillus parapertussis* is used.

Nasally Instilled Poliomyelitis Virus.—With a method of intranasal instillation of poliomyelitis virus that brings about infection of all *Macacus rhesus* monkeys subjected to it, Sabin and Olitsky determined the fate of nasally instilled virus in normal and convalescent immune animals. Control experiments revealed that the nasal mucosa of normal monkeys contained no observable antiviral factors and that virus could be detected when five or ten minimal cerebral infective doses were added to the mucosa. In the olfactory bulbs even a single infective dose could be recovered, since suspensions of both bulbs could be transferred to the brain of a monkey without any loss of material. After nasal instillation of virus in normal monkeys it disappeared quickly (four hours or less) and could be recovered neither from the excised nasal mucosa nor from the olfactory bulbs during the first forty-eight hours. At seventy-two hours, just before or coincident with the first rise of temperature, virus was found in small amounts in the nasal mucosa and for the first time also in the olfactory bulbs. At ninety-six hours, at least three days before the appearance of nervous signs, and later, while virus continued to be present in considerable amounts in the olfactory bulbs (and presumably elsewhere in the central nervous system), none was detected in the nasal mucosa. In convalescent immune animals receiving the same strain of virus intranasally which caused the original infection, none could be recovered from the nasal mucosa or central nervous system at four hours or one, two, three, four, five and seven days. The possible significance of these data from an epidemiologic point of view is in the suggestion that persons who are immune because of a previous attack of the disease (not to be confused with natural resistance, which perhaps determines whether an attack of poliomyelitis will be apparent or inapparent) may no longer act as transmitters of the same strain or type of virus infection.

Interstitial Cystitis and Lupus Erythematosus.—Fister states that a study of interstitial cystitis and lupus erythematosus shows that the two disorders seem to have many points in common and suggests that they are possibly phases of the same disease—the one occurring in the wall of the urinary bladder, the other in the skin. Interstitial cystitis and lupus erythematosus usually appear in the second to the fourth decades of life. Both diseases are more common in women than in men by a ratio of about 3:1. The two diseases appear to be about equally rare. It is difficult to explain why more cases of interstitial cystitis are seen in this country unless it is that physicians are learning to diagnose the disease more frequently in its early stages. Neither interstitial cystitis nor lupus erythematosus is caused by an invasion of the diseased tissue with tubercle bacillus. Lupus erythematosus in many cases, however, is found associated with tuberculosis, but the local lesion has none of the characteristics of tuberculosis of the skin. The theory of multiple etiology of lupus erythematosus is rather generally accepted and tuberculosis may be the focus of absorption in some cases. Interstitial cystitis is definitely a nontuberculous infection of the bladder, but in many cases the symptoms are suggestive of tuberculosis and it is important to rule out tuberculosis of the urinary tract. It is possible that a distant tuberculous infection may act as the foci of toxin for the vesical involvement. It is now generally agreed that the two diseases are the result of absorption of toxins from some focus of infection, and one of these may be tuberculosis. Infected teeth, tonsils, nasal sinuses, infections of the urinary tract or local pelvic infections may all be endogenic sources of toxin absorption. The toxin theory, however, does not explain all conditions, nor does the removal of an evident focus of infection cure all cases. Trauma, external irritations of the skin, a weak peripheral circulation, associated cyanosis, telangiectasis, chilblains and circulatory disturbances are apparently exogenic factors in some cases of lupus

erythematosis, while infections of the urinary tract, ureteritis, stricture of the ureter, perhaps childbirth, injury of the bladder, pelvic infections or circulatory changes in the wall of the bladder must be considered as possible additional factors in interstitial cystitis. The histopathologic changes of the two diseases are similar, but neither is of a specific character. Both have the characteristics of a chronic inflammation. The changes in the epidermis in lupus erythematosus are secondary to those in the corium and the changes in the mucous membrane in interstitial cystitis are secondary to those in the submucosa. Early in both diseases there is fibrous tissue hyalinization and fragmentation of the elastic tissue. In older lesions of lupus erythematosus, because of the progressive early changes, there results atrophy of the sweat and sebaceous glands, plugging of the follicles and atrophy of the epidermis, with an increase of the connective tissue and cicatricial formations. The later changes in interstitial cystitis consists of atrophy of the epithelium, various degrees of degeneration and ulcer formation. There is also proliferation of the connective tissue in the submucosa resulting in contraction of the vesical wall and cicatrization. Peripheral spreading of the infiltration with central degenerative changes occurs in the two conditions. Treatment of interstitial cystitis and lupus erythematosus has been along similar lines.

Testosterone Propionate in Hypogonadism.—Vest and Howard employed androgen (testosterone propionate) in five cases of primary testicular insufficiency due to castration, atrophy following trauma or an inherent defect in the testes and in one case of gonadal insufficiency secondary to demonstrable disease of the pituitary. Because of the known wide variation in the age of sexual maturation in man, their patients were only those with hypogonadism who were well past the normal age period of adolescence. Androgen seems to be a satisfactory replacement therapy for hypogonadism in the human being. It produces profound anatomic changes resulting in the proportionate growth of the phallus, scrotum, seminal vesicles and prostate, as well as development of pubic, axillary and extremity hair. There have been laryngeal changes (change to a more masculine voice), the appearance of considerable prostatic secretion and an ejaculum with coitus, and marked changes in the skin. There have been, in addition, changes in the general appearance, with improvement in the personality content. It has induced libido and potentia in persons in whom these had not existed previously, and restored normal sex life in a patient who was impotent following castration. No evidence of increase in tolerance to the drug has been observed.

Oxyuriasis.—One of the authors (Bozicevich) has reported an oxyuriasis incidence of 31.3 per cent on positive cases found by using only one NIH swab (stroking the perianal region with a glass rod tipped with a small square of cellophane and then examining the cellophane microscopically for pinworm eggs) on each of 230 boys at the Washington metropolitan police boys' camp during the summer of 1936. The investigation has been made again by Bozicevich and Brady during the summer of 1937 at the same camp, this time using repeated swabbings instead of one swabbing on 504 boys. Swabs were made on the boys the first thing in the morning before washing or defecating and often before dressing. Four swabbings were used in the examination of 329 boys, three swabbings for thirty-eight boys and two swabbings for 138 boys. In all, 289 persons harboring pinworms were found, an incidence of 57.3 per cent. Of these positives, 68 per cent of the cases were

found by the first swab; repeated examinations revealed the remaining 32 per cent. Swabs not taken on consecutive days will reveal more cases than the same number of swabs taken consecutively. Analysis of the incidence according to age does not show a definite correlation but suggests that the incidence begins to decline after the age of 14. Of the negative group the average family size was 5.5 and of the positive group 6.65. Large families appear to be a factor predisposing to a high incidence.

Localization of Intracranial Lesions.—In order to ascertain the value of electro-encephalography, Williams and Gibbs used the method in eighty unselected patients suspected of having intracranial lesions. The oscillograph records were made with an ink-writing instead of with a cathode ray oscillograph as used by Walter. Fifty of the patients gave abnormal cortical potentials with evidence of focal disturbance. The oscillograph records of seventeen patients showed no cortical abnormality, and in thirteen the records were characteristic of epilepsy, without any evidence of a constant focus of discharge of slow waves. In thirteen of the fifty patients with foci of abnormal discharge operation was not performed, and the clinical diagnosis was too indefinite to verify the accuracy of the observations. In the remaining thirty-seven cases verification of the position of the abnormality was possible. In twenty-two the lesion was seen at operation or necropsy, in ten its position was established by unequivocal clinical observations, confirmed in four by x-ray evidence and in five a bone defect was present in the skull as a result of previous trauma. In every one of these thirty-seven cases the position of the single focus of abnormal discharge corresponded closely with the site of the organic lesion. In the twenty-two cases in which the cerebral lesion was seen the correlation of the electro-encephalogram with the operative and postmortem observations was striking.

Reaction Expectancy of Neoarsphenamine.—According to Stephenson and his colleagues, the analysis of 541,381 administrations of neoarsphenamine to human beings from all medical services of the United States Navy, over a continuous period of five years, shows that the reaction expectancy increases with the age of the material. This clinical experience agrees with the laboratory observation that neoarsphenamine changes with age.

Vitamin B₁ in Leprous Neuritis.—During the last six months Badger and Patrick treated ten patients who had rather severe acute leprosy neuritis of the peripheral nerves with intramuscular injections of thiamin chloride. The injections were begun as soon as possible after the onset of symptoms or when the patient first complained of pain. The procedure followed was to give 300 international units once a day by intramuscular injection and twice a day by mouth. In the seven cases in which the injections were begun on the day of onset, the pain disappeared completely twenty-four hours after the first injection in four, in forty-eight hours in one and on the fourth day in another. In one case, owing to a required emergency treatment, the injections were discontinued after two had been given and on the third day the pain was moderate, after which it continued to lessen in severity until the seventh day, when it was no longer present. Tenderness could no longer be elicited after twenty-four hours in one and after three or four days in all but the one case in which the treatment was interrupted. In this case no tenderness could be elicited on the seventh day. In each case the tenderness was less marked twenty-four hours after the first injection. Definite diminution in the swelling occurred about the time the tenderness disappeared. In one case the injection treatment was begun on the second day of symptoms, and twenty-four hours later the pain lessened definitely. The pain disappeared entirely after

three injections, and after four injections the tenderness disappeared completely. In two cases the injections were begun on the fourth and fifth days of symptoms. In the former the response to treatment was not as abrupt and the improvement was not sharply defined from day to day. In the other case the results were about as prompt as in the majority of the cases.

Diagnosis of Pylorospasm and Ruptured Peptic Ulcer.—Wolfe reports five cases of acute pylorospasm, four patients being women and one a man. All were suffering with intense agonizing pain in the epigastric region. Examinations showed tympany over the stomach, varying degrees of shock, fixed attitude and tremendous anxiety. The abdominal wall in each case was tense and the character of the pain might easily have been confused with that caused by ruptured peptic ulcer. Tenseness of the abdomen differed from that of ruptured peptic ulcer because of the fact that it was slightly more yielding to palpation and not as rigid and boardlike as that caused by the latter condition. Five minims (0.3 cc.) of a 1:1,000 solution of epinephrine was given hypodermically to every patient and this produced marked relief of the spasm in the women within five minutes. In the man three doses at intervals of five minutes were required before the spasm began to subside. Acute pain from peptic ulcer due to local reflex spasm in the muscle fibers underlying the ulcer might be relieved and perforation prevented by the hypodermic use of epinephrine. If these patients were suffering from perforations, epinephrine would have had no effect. The use of epinephrine was prompted by the author's appreciation of the similarity of the neurophysiology involved in spasm of the digestive tract and of that in bronchospasm. Its use involved no risk and would have caused no delay had these been cases of ruptured peptic ulcer.

Transfusion with Stored Blood.—Wilson and Jamieson give the details of fourteen instances (ten patients) of blood transfusion exemplifying the value of having a supply of blood in cold storage, ready for immediate use. The indications for transfusion were weakness and anemia associated with sepsis and malignant disease rather than the replacement of blood lost through hemorrhage, which was present in only three instances. Two deaths occurred in the period immediately following transfusion, one from syncope and the other from recurrence of hemorrhage. In three other cases the outcome was eventually fatal. None of these cases showed any reaction in the immediate post-transfusion period, and in no case could the fatal result be attributed to the administration of stored blood. Five of the patients—comprising eight transfusions—are alive after more than a year has elapsed. Among these are the two patients in whom reactions occurred. The procedure is a safe one.

Intradermal Tests in Diabetes Mellitus.—Seelig performed the intradermal test in fifty-one patients, of whom twenty were suffering from diabetes mellitus and thirty-one from diseases other than diabetes mellitus. On each flexor surface of the arms intradermal wheals were produced by an injection of 0.5 cc. of physiologic solution of sodium chloride and 0.5 cc. of a 0.1 per cent solution of dextrose, respectively. The time of disappearance of the wheals was compared. The results of the tests in the diabetic patients were uniform. In nineteen of the twenty cases the dextrose wheals disappeared more quickly than the ones caused by saline solution. If one assumes that the time of disappearance of an intradermal wheal containing a certain substance which is a constituent of the blood is indicative of the avidity of the skin for that substance, one may conclude that the skin of the diabetic patient has an

increased avidity for dextrose. In no case of a group of twenty subjects not suffering from diabetes mellitus did the "dextrose wheal" disappear either before or at the same rate as the saline one. There remains a third group of patients, who though not diabetic show results which are identical with the "diabetic" type of reactors. Two persons in this group were highly dehydrated, while the other nine were suffering from conditions which may have a bearing on the water and sugar metabolism.

*Femoral Thrombosis. R. T. Payne.—p. 1214.

Chemotherapy of Infections.—Whithy finds that 2-(p -aminobenzenesulfonamido) pyridine possesses great chemotherapeutic activity against pneumococci of several types, more especially types I, VII and VIII, and also gives considerable protection against types II, III and V. Whereas most observers have found it easier to protect against type III than against type I, the reverse has been the case in the present series of experiments. The substance is not only highly protective against the Richards strain of hemolytic streptococcus in mice but is efficient in doses as low as from 1 to 2 mg. per gram of body weight of mice. The substance is active against meningococci. It appears to have a more polyvalent action than sulfanilamide, to be effective in low dosage and to have the great advantage, according to animal experiment, of being of low toxicity. There is evidence that it does not produce porphyrinuria. These experiments represent the one striking success in the chemotherapy of pneumococcal infections in an assessment of sixty-four related sulfanilamide compounds, some soluble, others insoluble.

Femoral Thrombosis.—Payne discusses a series of eighty-five cases of femoral thrombosis occurring in 1,300 cases of peripheral vascular or lymphatic disease. In all of these there was a definite cause, an acute onset and a varying period of disability. The thrombosis was associated with parturition or abortion in thirty-nine (with the postoperative state in seventeen), with typhoid in twelve and with infections of the lungs or pleura in seven. The remaining cases were associated with influenza, phlebitis, fracture, ulcerative colitis and erysipelas. The condition was bilateral in twenty-one cases, and in the unilateral cases the right side was involved in eighteen and the left in forty-six. In no patient in the entire series did the limb return entirely to normal. In two cases the evidence suggested a pure thrombosis, in sixty-one a pure lymphangitis and in twenty-two a combination of thrombosis and lymphangitis. Ulceration of the limb was present at some time or other in twenty-six of the eighty-five cases. These ulcers were chronic and intractable and associated with extensive inflammatory changes. Attacks of phlebitis occurred in nine cases, either in single attacks or in the form of recurrent attacks. It is estimated that some 5,000 cases of femoral thrombosis occur

annually in this country. The clinical evidence supports the view that lymphatic obstruction is responsible for the edema which is a characteristic feature of femoral thrombosis at all stages of the disease. From the experimental evidence, venous ligation will not produce edema. In patients dying as the result of a pulmonary embolus, the embolus is, as a rule, the first and final manifestation of a latent thrombosis, and but few of these patients have had the clinical manifestations of an antecedent "white leg." In cases of manifest femoral thrombosis a perivenous lymphangitis is the primary condition and this is followed by phlebitis and secondary thrombosis of the vessel. In these circumstances the thrombus is closely adherent to the wall of the vessel. In latent thrombosis that is without clinical manifestations the thrombosis is not associated with any perivenous change and the clot is but lightly adherent to the vessel. For this reason emboli are likely to occur.

Pituitary Basophilism.—Pattison and Swan describe two cases of Cushing's syndrome in young women in whom improvement followed the insertion of radon seeds into the sella turcica. Both patients proved resistant to high voltage roentgen therapy and, in view of a progressive increase in blood pressure and the presence of gross osseous decalcification in the second patient, operation was considered to be justifiable. Although in the first patient no histologic confirmation of the pathologic condition is available there is no reason to doubt, on clinical grounds, that the case was a typical one of Cushing's syndrome. In the second patient the possibility of an adrenal tumor had been excluded by means of an exploratory laparotomy and the demonstration of the Crooke hyaline change. The relief from osseous pain that followed immediately after the implantation of radon seems to be analogous to that which may follow the removal of a parathyroid tumor in generalized osteitis fibrosa. The blood sugar curve showed a closer approximation to normal after operation than in the first patient, but the reduction of blood pressure and the hemoglobin percentage were approximately the same in the two patients. The implantation of radon has not provided a "cure" for the syndrome. On the other hand considerable improvement has followed the operation, and the menace of a progressively increasing blood pressure no longer exists. The disability resulting from osseous decalcification in the second patient has disappeared after the implantation of radon. The results following the use of 9 millicuries of radon in the second patient were not strikingly different to those following a dosage of 4 millicuries in the first patient, but the seeds in the first case were more favorably placed for influencing the activity of the pituitary, owing to the shape of the sella turcica. Although both patients are in a state of excellent subjective health their external configuration has been little altered. The general appearances are however much improved as a result of the disappearance of hirsutism of the face. In view of the doubtful part played by the basophil adenoma in Cushing's syndrome, it is the authors' opinion that treatment which aims at removing such a tumor is not rational.

Immunization Against Influenza.—Fairbrother finds that elementary body suspensions, heated at 57 C. for from thirty to forty-five minutes, constitute a useful immunizing agent against infection with the virus of influenza. The results obtained with mice and ferrets suggest that any differences given by the heated and living vaccines were due mainly to variations in the concentration of the virus in the suspensions. An appreciable antibody response was obtained by the inoculation of human volunteers and also a rabbit. These results suggest that heated elementary body suspensions should constitute an admirable immunizing agent for general application. Immunity following an attack of influenza is of only short duration. As there is no reason to suppose that artificially induced

immunity will be as great as that following infection, specific prophylaxis is not likely to be beneficial except under certain circumstances. It appears necessary either to give a series of injections during the late autumn—i. e., before influenza usually occurs—or to wait until an extensive epidemic is expected. Protection is to be expected only against epidemic influenza and not against the sporadic forms, many of which are vague infections of the upper part of the respiratory tract. In order to control the efficacy of the vaccines, serologic tests should be carried out before and after inoculation.

Vaccine Treatment of Diphtheria Carriers.—Since the harmful action on the cell of *Corynebacterium diphtheriae* depends on antibacterial immunity, it is theoretically logical to treat carriers or patients whose throats persistently harbor the diphtheria organism with diphtheria vaccine. Yu and Towers made throat swabs from 120 nurses and cultures of these were taken for *Corynebacterium diphtheriae*. Two of the nurses were found to be healthy carriers. Among the cases of clinical diphtheria, the throats of six continued to show positive organisms with delayed resolution of *Corynebacterium diphtheriae*. *Corynebacterium diphtheriae* isolated in these eight cases were all smooth. With the exception of a culture isolated from a healthy carrier which was avirulent, the remaining seven cultures were all virulent. Each of these six carriers received 5,000 units of antitoxin, were kept in the isolation ward and were found carrying *Corynebacterium diphtheriae* for a period of from one to four months. The diphtheria vaccine used in this experiment was prepared from a smooth virulent strain of *Corynebacterium diphtheriae*. The two healthy carriers and the six convalescents were subjected to vaccine treatment, commencing with 0.2 cc. of vaccine (approximately 100 million organisms) injected subcutaneously. The strength of each subsequent injection was doubled. The interval between injections was three days. Throat swabs were made after each injection and cultures taken for *Corynebacterium diphtheriae*. Two patients were cured after the fourth injection of vaccine, while the rest cleared up after the fifth injection. A bactericidal test was performed by taking blood from vaccine treated persons before giving vaccine and two weeks after the fifth injection. The results demonstrate that the bactericidal power toward *Corynebacterium diphtheriae* is increased by vaccine treatment.

Vitamin B₁ in Diet and Question of Bread. H. Muller.—p. 475.

Chronic Pancreatitis of Atypical Evolution: Three Cases. J. Lorient.—p. 495.

Pancreatic Juice in Infectious Diseases.—Garofeanu points out that the older methods of examination of the diastasic activity of the pancreatic juice contained sources of error and that now only the direct method is regarded as suitable. This method consists in the examination of the fermentative activity of the enzymes in the duodenal juice, withdrawn following provoked secretion. This method discloses not only severe glandular changes but also the slight lesions of the gland which are likely to appear in diverse disorders. After citing the conditions in which this method has been employed by other investigators, the author says that he himself used the biologic examination of the duodenal fluid to determine the diastasic activity of the pancreatic juice in the course of infectious diseases. These researches were made on juice obtained after secretion had been provoked by ether and after preliminary evacuation of the bile following an intraduodenal injection of magnesium sulfate. The author cites the difficulties that are encountered in this method, particularly with the tubage and the introduction of ether. The latter provokes salivation, redness of the face, nausea, tachycardia and attacks of coughing. The author made his investigations on twelve patients with infectious diseases such as exanthematous typhus, typhoid, paratyphoid, scarlet fever, erysipelas, anthrax and influenza. To determine the fermentative activity of the lipase, he resorted to Bondi's method in the modification of Chiray and Milchevitch; for the evaluation of the diastasic activity of the trypsin he used the method of Goiffon and Nepveux. The results obtained with the latter method are recorded in two tables; the first one reveals the diastasic activity during fever and the second one during convalescence. The enzymatic activity showed a reduction, at least in certain cases, and the quantity of the duodenal juice was always diminished. The activity of the lipase was reduced in six of twelve cases; this reduction was most noticeable in two cases of exanthematous typhus and in one case of erysipelas. As regards the activity of the trypsin, it was diminished in five of twelve cases, the diminution being greatest in two cases of exanthematous typhus and in one case of paratyphoid A. Thus the reduction in the diastasic activity concerns the lipase or the trypsin or both. It is sometimes caused by the febrile state but in the majority of cases is due to an impairment of the gland.

Injections of Blood in Rheumatic Pains.—Autohemotherapy, Le Calvé states, elicits a mild shock, which is well tolerated, increases the immunity, stimulates the reticulo-endothelial system and desensitizes the organism against certain anaphylactic conditions. These factors make it logical to employ this treatment in rheumatic conditions, which are mostly allergic manifestations. Moreover, in rheumatism of Bouillaud's type, in which the author found that treatment with a sulfurated oil and sodium salicylate produces a more rapid improvement than did medication with salicylate alone, he observed also that he could obtain the same results by autohemotherapy together with several injections of the sulfurated preparation. In this connection the author cites the histories of two boys, aged 13 and 14 years, who had acute articular rheumatism. The first attack confined them to bed for twenty-five days and six weeks, respectively. Both presented the symptoms of endocarditis. During a second attack, a year later, two applications of autohemotherapy cured one in nine days, the other in six days.

Another argument in favor of autohemotherapy is that it often exerts a calming influence on the pains. This action is especially noticeable when the reinjection of the blood is made into the painful zone. Still another consideration is that the albumins of the blood, extravasated in the tissues, are there subjected to the attack of proteolytic ferments. Digested and disintegrated, they are transformed into peptides, then into amino acids and in aminated bases with a predominating hypotensive action. Moreover, autohemotherapy provokes vasodilatation, a slight acceleration of the pulse and a reduction in the tension, and it exerts an influence on the nerves. It appears that the action of autohemotherapy, particularly its analgesic effects, are due to the liberation of histamine or of a related body. The disintegration of the injected blood does not take place suddenly but gradually, and the therapeutic action is thus prolonged. The author says that the number of intradermal injections varies: one or two injections, at a distance, of 2 or 3 cc. may be made at the painful points and several others around the area. At the same session, several regions may be treated. The rest of the blood can be injected into the buttock. The author cites the clinical histories of some of the cases in which he resorted to hemotherapy. In forty-two cases he found that the combination of autohemotherapy with injections of sulfurated oil produced better results than did the injection of the sulfurated oil alone, but he also obtained several cures by employing hemotherapy alone.

Osteomyelitis with Friedländer Bacillus.—Talbot and Parlange say that the pneumobacillus which was described by Friedländer in 1882 has for a long time been confused with the pneumococcus. This confusion can be explained by the presence of a capsule in both of them and by the fact that either may be present in pathologic processes of the lung. The septicemia with the pneumobacillus is encountered most frequently in the adult. It does not always exhibit the same clinical aspects, but most often it appears in the form of a pure septicemia without local manifestations. In other cases this septicemia is chiefly localized; it may be pulmonary or meningeal or it may become manifest in the form of a hepatocholecystitis, adrenalitis or aortitis. Moreover, the pneumobacillus has been known to cause septicopyemia. The authors observed a case of septicopyemia with the pneumobacillus of Friedländer, which was of otitic origin, with sinojugal thrombophlebitis and multiple localizations, one of which was an osteomyelitis. Osteomyelitis with Friedländer's bacillus is a rare disorder and is always grave. It is of an extremely tenacious character in that it reappears after apparent cure. The authors differentiate four anatomicopathologic forms of the osteitis caused by the Friedländer bacillus: (1) a periosteal form with abscess, (2) a form in which under the periosteal abscess an osteomyelitis was discovered, (3) a massive osteomyelitis and (4) a form of dry diaphyseal caries. To the question whether the osseous processes caused by the Friedländer bacillus present characteristic symptoms that would facilitate the diagnosis and treatment, they give a negative reply. However, the torpid evolution should call attention to this type of process. The authors show that it is impossible to give general directions about the local treatment because practically all measures have been known to produce cure in one case and have been followed by death in others. The various types of shock therapy, they state, have so far been without appreciable results. Acriflavine hydrochloride has been used successfully by some investigators in septicemias with the pneumobacillus; moreover, some derivatives

of sulfanilamide have proved successful against some capsulated organisms. They themselves observed a rapid effect in the treatment with mandelic acid. They think that in the future chemotherapy will be of great importance in the treatment of pneumobacillary processes.

Disease of Swineherds.—Georgi and his associates point out that one of them described the first case of the "maladie des jeunes porchers" (disease of young swineherds) in 1931 and that since then the reports about this type of disease have multiplied. During the first eighteen months following the discovery of this disease they never had an opportunity to treat a relapse, and they were of the opinion that the first attack of the disease conferred an immunity. Recent observations, however, caused them to change their view. They cite six cases of the disease of swineherds in which relapses or recurrences developed. All the patients were cured without sequels, but in several cases the disorder was so grave that the differential diagnosis had to consider the possibility of meningitis, beginning septicemia, Brucella abortus infection or typhoid. The anamnesis, which directed attention to the occupational type of disease, had an important part in determining the correct diagnosis. Discussing the transmission of the disease, the authors say that they never observed contagion from man to man. All the persons who developed the disease were people coming in contact with hogs. In taking up the terminology of the disease the authors suggest that it be referred to simply as disease of swineherds rather than of "young" swineherds. Knowing the benign character of the disease of swineherds, they decided to use it as a substitute for malaria in fever therapy in the treatment of schizophrenia. In the course of these inoculations it was found that, just as in the animal experiments, the first inoculation produced fever but the subsequent ones did not. From these observations the authors conclude that the experimental inoculation confers immunity, of what duration is as yet unknown. After the spontaneous disease, however, the immunity is not always complete and lasting. In the concluding summary the authors say that the disease of swineherds is caused by a filtrable virus which is transmissible to man and animals. In man the period of incubation varies between six and thirteen days.

Hemolymphopoietic System in Psoriasis.—Cottini studied nineteen patients with psoriasis by a histopathologic study of lymph nodes removed by biopsy. The superficial lymph nodes are enlarged, hardened, painless and mobile. The enlargement parallels early evolution of the disease and stops as the latter enters the period of chronicity. Periadentitis is not present. Lymph nodes of the inguinal and axillary regions are the most frequently involved. The most interesting facts are the presence of eosinophilia, proliferation of the reticulo-endothelial cells of the lymph nodes and the presence of large deposits of pigments in the adenoid tissue. Eosinophilia is acute in the sternal bone marrow, taken by puncture, and moderate in the peripheral blood and the skin and lymph nodes. It is due to an allergic reaction of the sternal bone marrow to disintegrated cells. The reticulo-endothelial cells at the lymph nodes have a characteristic distribution and phagocytic properties. Tissues of the medullary

portion are almost replaced by fibroblasts, especially near the hilus. The cortical portion is almost normal. It is the seat of a large number of phagocytes which contain melanin. The changes of the lymph nodes are acute in patients who have had the disease for a long time. The author feels that the metabolism of the skin and the interchanges between the skin and the epidermis are disturbed in the course of psoriasis. The disorder results in an increased passage of pigments to the lymph nodes. The latter react with proliferation of reticulo-endothelial cells with increased properties of fixation of the pigments.

Appendicitis and Biliary Stasis.—Brandão Filho and Vilela Pedras say that many patients who had an appendectomy for chronic appendicitis report a continuation of the gastric disorders. The microscopic study of the removed appendixes confirms the indications of appendectomy. According to the authors, biliary stasis, which frequently coexists with chronic appendicitis, is the cause of the continuation of the gastric disorders after appendectomy. It is advisable to make an early diagnosis and treat the condition. Treatment consists in biliary drainage by Meltzer-Lyon's therapeutic test and administration of substances which stimulate the motor function of the gallbladder. The number of duodenal intubations varies from six to twelve. It is ruled by disappearance of the biliary stasis, which is verified by repeated roentgen examination of the gallbladder. The results of the treatment depend especially on early administration. If it fails, a surgical intervention on the gallbladder is indicated. Three cases are reported.

Pathogenesis of Joint Mice in Talocrural Joint. H. Puhl and K. Lindemann.—p. 726.

Surgical Treatment of Habitual Dislocation of Shoulder.—Heep reviews the various surgical methods that have been recommended for the treatment of the habitual dislocation of the shoulder joint. He says that the operations on the muscles have been largely abandoned because they do not produce the desired results, and the simple ruffing of the capsule has likewise been discontinued because there are frequent relapses. Even the normal capsule is rather wide at the shoulder joint, so that it does not have the essential part in the habitual dislocation. The preferred therapeutic methods today are the interventions on the bone, and of these the extra-articular ones seem to be the best. At the author's clinic, Eden's operation is employed. This operation consists in the transplantation of a piece of the tibia into the anterior border of the glenoid cavity. The piece of bone must extend at least 1 cm. beyond the anterior border of the glenoid cavity. It must be covered with periosteum and must be fixed on the lower border of the glenoid cavity. This is accomplished either by means of periosteal sutures or by fixing the piece of bone to the neck of the scapula by means of a bone screw. Follow-up examinations one, two, three and five years after the intervention revealed that the results obtained with Eden's operation are quite satisfactory. The advantage of the operation is that it is an extra-articular intervention which makes the opening of the joint unnecessary. A disadvantage of the operation is that the approach to the

anterior portion of the glenoid cavity is rather difficult, particularly in obese persons. Moreover, the fixation is not easy. However, an experienced and competent surgeon will readily overcome these technical difficulties. The author reviews the clinical histories of six patients in whom this operation was performed. The last of the cases demonstrates that exactness is essential, for if the transplanted piece of bone does not extend beyond the anterior glenoid border the operation is a failure, because the piece does not act as a barricade.

Erythema Nodosum and Tuberculosis in Adults.—

Following a review of the literature on the relation between erythema nodosum and tuberculosis, Zweifel reports his own observations in fifty-six cases of erythema nodosum which were observed at the medical policlinic of the University of Zurich during the years 1931-1936. The ages of the patients varied between 13 and 49, but the majority of the patients were about 20; forty-eight were females and eight were males. After citing some of the symptoms, such as the initial fever, the first appearance of the erythema on the anterior surface of the lower part of the leg or on the forearms and the painfulness of the nodules only on pressure, the author discusses, among other factors, the outcome of the tuberculin reaction, the concurrence of erythema nodosum with disorders of other organs and the results of the roentgenoscopy. In summarizing his observations, he says that of the forty-three adults in whom a roentgenogram was made twenty-two (51 per cent) presented tuberculous processes. These were nearly always of the type designated as "secondary infiltrations." In ten other cases (23 per cent) the changes were slight or questionable. In the other eleven cases (26 per cent) roentgenoscopy gave negative results. However, the author thinks that in the last two groups there may be cases in which the roentgenoscopy was made either too early or too late. If six additional cases (described by another author) and the case of a child are counted in, the percentage of the simultaneous occurrence of erythema nodosum with florid tuberculous pulmonary changes in the roentgenogram amounts to 56. In three cases relapses of erythema nodosum were observed. In ten cases articular involvement was observed, which in the presence of the roentgenologic aspects of the lungs was regarded as "Poncet-rheumatism" in the presence of erythema nodosum. The author states further that twenty-six positive tuberculin reactions were observed in thirty-three patients with erythema nodosum. It is noteworthy that in six of the seven patients with erythema nodosum who reacted negatively to the tuberculin test the roentgenogram indicated a tuberculous origin.

*Pheochromocytoma of Adrenals: Concurrence with Neurofibromatosis. F. Brenner, H. Konzett and F. Nagl.—p. 914.

Gudzent's Test in Rheumatism and Gout.—Tancre admits that Gudzent's test method for rheumatism has been criticized by some investigators because many patients without rheumatism give positive reactions, whereas some with rheumatism give negative reactions. Moreover, some clinicians are of the opinion that rheumatism has no connection with allergy but is the result of infection. The author thinks that both theories, that of the exclusive allergic origin as well as that of the exclusive infectious origin, are too narrow. He emphasizes that the clinical aspects of rheumatism show such a great variety that a

narrow etiologic interpretation is not justified. On the basis of his practical experiences he is convinced that the assumption of an allergic etiology of rheumatism is of great value. A large number of disorders, among them rheumatism, may result from an allergic condition. To be sure, it cannot be expected that in each rheumatic patient a positive reaction will result from Gudzent's allergic tests. However, in about 30 per cent of the patients with rheumatism, positive reactions are obtained which make it possible to identify the harmful factor. The exclusion of this factor may effect cure or improvement. The author does not deny that infections and exposure to cold may be causal factors in the development of rheumatism. In this connection he points out that tests on rheumatic miners yielded hardly any positive allergic reactions and he thinks that in these miners the rapid changes in temperature to which they were exposed may have been a causal factor in the rheumatism. The author employed the so-called allergenins of Gudzent in seventy patients with rheumatism and gout. The tests include those with meat, cereals, fish, milk, eggs, vegetables, bacteria, mold and control solution. The author gives brief clinical histories of several patients in whom positive reactions were obtained and in whom the exclusion of the offensive substances was followed by cure or improvement. He was able to prove that Gudzent's allergenins produce strictly specific reactions. Some of the patients gave positive reactions to one or two tests and negative reactions to all others. He emphasizes once more that in allergic tests on rheumatic and gouty patients, just as in the other so-called allergic disorders, positive results can be expected only in a certain percentage of the patients.

Pheochromocytoma of Adrenals.—Brenner and his associates consider the report of one case of chromaffin tumor of the adrenals justified because this case differs in several respects from those reported in the literature. The patient, a woman, did not present the symptoms that are characteristic for this type of disorder, and the multiplicity of symptoms made a diagnosis difficult. The condition of the urine, the hypertension and the changes in the fundus oculi suggested an acute nephritis. However, there were also several aspects which could not be explained on the basis of a renal disorder, and some symptoms of renal disease were lacking. Periarteritis nodosa was another disorder that was taken into consideration. The necropsy disclosed, besides other pathologic changes, a pheochromocytoma originating in the medullary cells of the left adrenal. The tumor weighed 300 Gm. What makes this case especially interesting is the concurrence of a chromaffin tumor of the adrenal with a neurofibromatosis. In this connection the author points out that the simultaneous occurrence of these two conditions has been reported repeatedly. Among the sixty-four cases of chromaffin tumors of the adrenals hitherto reported, there were eight in which neurofibromatosis existed simultaneously. This concurrence of the two disorders has been regarded as the manifestation of a systemic disease of the nervous system in which brain, spinal cord and peripheral nerves as well as the sympathetic and its derivatives may be involved. The authors also determined the epinephrine content of the tumor and found it exceptionally high. They think that this explains the high blood pressure and the tachycardia which were observed in the woman.

Intracranial Complications of Otitis Media. W. Jankowski.—p. 568.
New Methods of Therapy of Infections. N. Dab.—p. 573.

Radium Therapy of Myoma of Uterus.—Seidler reports thirty-nine cases of myoma of the uterus observed during the last four years in which radium treatment was administered. He used radium in cases in which surgical intervention was contraindicated either because of severe anemia or because of hemorrhage. Hemorrhages were immediately stopped by application of radium. In one case the myoma was as large as a hen's egg, with severe hemorrhage, but after the administration of 3,600 mg. hours the hemorrhage was stopped. Myoma occurred in twenty-nine multiparas and ten primiparas. He separated them according to age in three groups: In group 1

there were three patients ranging in age from 20 to 30 years, in group 2 there were twenty-five patients from 30 to 40 and in group 3 there were eleven patients over the age of 40. The dosage was from 930 to 5,000 mg. hours, according to the age and size of the tumor. The mortality rate after operation is from 2 to 5 per cent and after radium therapy about 0.2 per cent. The genital organs of the patient are saved and the hormone action reappears after a few months.

Use of Metals in Surgery. A. H. Smook.—p. 3080.

Fatality Following Treatment with Insulin Shock According to Sakel: Method. A. P. Timmer.—p. 3088.

Aleukemic Megakaryocytic Myelosis.—Lindeboom points out that in the group of aleukemic leukemias a form has been recognized in which the pathologic anatomic examination of the spleen and liver disclosed giant cells. These giant cells have been considered to be megakaryocytes and the disorder has been designated as aleukemic megakaryocytic myelosis. In recent years it has been suggested that this disorder presents an independent disease entity. It develops mostly in middle-aged persons, more often in women than in men. It is a chronic disease which develops insidiously. The enlargement of the spleen, which is usually considerable, dominates the clinical picture but its discovery is usually accidental. Fatigue, enlargement of and a sensation of heaviness in the abdomen and piercing pains in the region of the spleen are the chief complaints. The enlargement of the liver is usually much less noticeable than that of the spleen. The lymph nodes are not swollen. The temperature may be subfebrile. The examination of the blood usually reveals a mild to moderate orthochromic or hypochromic anemia, which during the later stages may become more severe. The resistance of the erythrocytes is often somewhat reduced. The number of leukocytes may be entirely normal or they may be slightly reduced or greatly increased. In nearly all cases a more or less severe myeloid reaction is noticeable. The considerable polychromasia and the anisocytosis and poikilocytosis are surprising in view of the moderate anemia. The author reports the clinical histories of two patients who had this disorder. Discussing the placement in the nosologic system, the author doubts that the disorder can be classified with the leukemias and suggests that it stands between the leukemias and the pure endothelioses and is a hepatolienal hematopoietic endotheliosis. Regarding the treatment, he says that the effect of roentgenotherapy is usually slight. In one of the reported cases it was followed by a temporary improvement. The splenectomy caused no improvement, for the condition of the patient was less good than it had been before the operation. However, the French literature reports some successes with this treatment and recommends the early removal of the spleen.

Bacterium Alkaliescence in Infections of Urinary Tract and Its Relation to Dysentery Bacilli. E. Neter.—p. 597.

Icteric Form of Glandular Fever.—De Vries does not consider glandular fever to be a rare disease nor does he think that the cases corresponding to Pfeiffer's original description are the most common. Careful clinical studies have disclosed widely different types which have certain distinct characteristics in addition to the main symptoms of the disease: fever, general adenopathy and lymphomononucleosis. Atypical forms of glandular fever were first recognized by Glanzmann and Tidy. The three aforementioned characteristic symptoms are not necessarily present in the atypical cases. Fever and adenopathy have been known to be absent or to be present in only a mild degree. Although some authorities hesitate to recognize glandular fever

in such a form, the author believes that, although rarely, the disease does occur in such a form. The diagnosis is dependent on two essential factors: (1) the typical morphologic blood picture and (2) the positive antibody test of Paul and Bunnell. Following a discussion of these hematologic and serologic aspects, the author reports the clinical histories of three cases which illustrate the value of the hematologic and serologic examinations, since the clinical signs alone would have suggested the diagnosis "jaundice." Neither fever nor adenopathy was sufficiently prominent to seem of value for the diagnosis. The author says that in the future in every case of jaundice a blood count and the antibody test of Paul and Bunnell should be made. In true infectious jaundice, as opposed to infectious mononucleosis, a leukopenia with lymphocytosis and deviation toward the left without atypical cell types, without pathologic changes in the lymphocytes and with a negative Paul and Bunnell reaction will be found.

Pregnancy Complicated with Diabetes.—Brandstrup and Okkels point out that the literature on diabetes and pregnancy from the preinsulin days gives a gloomy outlook for the mother as well as for the child. There was a maternal mortality of 30 per cent in direct connection with pregnancy or parturition, and not more than 50 per cent of these patients were alive as long as two and a half years after the parturition. As to the children, the outcome was even worse, as abortion, intra-uterine death of the fetus and death of the child during delivery or within the first days of life occurred so frequently that the total death rate for the fetus exceeded 60 per cent. The discovery of insulin has brought about a complete revolution. Young women with diabetes do not die of diabetes, and they conceive far more frequently than before. While it is possible with modern therapy to make the female diabetic patient free from symptoms, enabling her to work and to conceive, it is not always practicable to bring her safely through pregnancy and parturition. The material here presented comprises twenty-two instances of pregnancy in nineteen diabetic patients observed in the Lying-in Department A, Rigshospital, Copenhagen. This material is not suggestive of any change in the diabetic condition of the mothers during pregnancy. The restitution of these patients after the puerperium indicates that such changes as have been observed during pregnancy (frequency of acidosis and changes in the insulin requirement) are attributable to factors of a nature that does not directly concern the diabetic condition. The obstetric risk is somewhat increased through a tendency to hydramnios, excessive size of the child and, especially, infection in the presence of eczema of the vulva. In the twenty-two cases observed, only ten living children were discharged from the hospital. The great mortality among children of diabetic patients may probably be attributed to maternal hyperglycemia and acidosis. In three of the dead children the necropsy was extended to include a thorough microscopic examination of the endocrine organs. The pathologic changes observed in the pancreas, hypophysis and thyroid are described. Commenting on these changes, the authors say that the maternal hyperglycemia alone brings about the pathologic changes in the child. In the discussion of the therapeutic problems, it is pointed out that in the future the main task of the treatment should be to employ such dietetic and medicinal measures as to make obstetric operations unnecessary. The pregnant diabetic patient must be watched closely, and the efforts must be aimed at the avoidance of hyperglycemia and acidosis. The therapeutic significance of protamine zinc insulin is emphasized.

SOME NEUROLOGIC ASPECTS OF PSYCHIATRY

CHAIRMAN'S ADDRESS

SAMUEL D. INGHAM, M.D.

LOS ANGELES

Psychiatry, as a department of medical science, has been having a hard time keeping pace with the other departments of medicine, and it is commonly accused of being unscientific, of being a philosophy rather than a science. With the present day progress in psychiatric research, this indictment is no longer a true one, and the science of psychiatry bids fair to assume a leading position by its contributions to the welfare of the human race.

Modern psychiatry, the science of human behavior, has been built as a superstructure on the foundation of psychology, neurology and biology. Until recently neurology and biology have contributed comparatively little, and psychology has taken the leading role as a basis for psychiatric observations and analyses. In the past half century since Bastian wrote "The Brain as an Organ of Mind," neurology and biology have made notable advances and have furnished data by means of which it is possible to find more and more correlations of structure and function as regards the brain, and a better appreciation of the physical basis of human behavior.

The superstructure of psychiatry is far from being completed and there is no prospect that it ever will be, but more advancements are being made today than ever before. Many research workers are constantly contributing new material in the basic sciences, others are consolidating the material and fitting it into the foundation, while still others are improving the general architecture of the superstructure and harmonizing its different departments that each may be more useful to the others. Today more than ever before psychology, psychiatry and neurology are interlaced and interdependent, and workers in each of these special fields are not only adopting material from the others but are contributing valuable material to the others.

From the time when the human race was endowed with intelligence sufficient for introspection and came to realize that man was born to die, philosophers have struggled with conceptions of the soul and the body and of the relationship of mind to matter. Only during the past century has the conception developed that the mind is not something apart and independent of the body, but today it is generally conceded that, in the last analysis,

all thought and all behavior are the results of physical and chemical reactions in living tissues. It is with this point of view that neurology seeks to find correlations of structure and function with regard to mental processes as well as in the sensory and motor phenomena, in which so much success has been attained.

Neurology deals primarily with the correlations of structure and function, utilizing all available evidence from biology and the contributory sciences. It has largely ignored the analysis of personality and has preferred to study physical phenomena, thus exposing itself to the charge of being "materialistic." It is my purpose in this discussion to review briefly some of the concepts of neurology with regard to the problems of psychiatry, although such concepts are admittedly in part theoretic and hypothetic.

Among the contributions of biology, the theory of neurobiotaxis developed by Kappers deserves consideration here in view of its apparent applicability in explanation of the development and functioning of the nervous system. According to this theory activity in living cells causes electrical polarization, and in nerve cells this is an important factor in the formation of the cell processes. The axon develops from the positively charged part of the cell, a nodal point, and the dendrites from the negative surface, which is undifferentiated. The processes continue to extend until synapses are established, the axon growing in the direction of the predominating action currents and the dendrites toward the source of action currents which reach the cell from outside. This process is not only active during the period of embryonic development but continues throughout life and is apparently an important factor in the formation of synapses and in the building up of "engrams." If this theory is valid it goes far to explain on a physiologic basis the processes of memory and learning, the formation of habits of thought and action, and the mechanism of conditioned reflexes and of mental activities in general. It also contributes evidence in support of the theory of inheritance of acquired characters in the evolutionary sense so far as the anatomic arrangement of cell groups and fiber tracts of the nervous system seem to have shifted in the course of evolution in conformity to this theory and have become established by heredity. Kappers states: "This fundamental law of neurobiotaxis not only shows that the well known law of association in psychology is a neurobiotactic law, but it also indicates how wonderfully polarized is the whole process of tract formation, and how well this process fits into the class of bioelectric phenomena" and "This law has long since been acknowledged to be one of the major laws governing the development of our mental capacities, that is, the law of mental association."

The theory of neurobiotaxis has been utilized in the development of the following concepts as a supplement to the well known principles of neurophysiology and cerebral localization.

CONSCIOUSNESS

The neurologic concept of consciousness is that it is a state of activity of the entire nervous system, and in particular of the brain, which varies quantitatively from the maximum degree of mental action to complete inactivity, as in coma or general surgical anesthesia. Although all parts of the brain may contribute to the mental processes during consciousness, mental activity of all kinds appears to depend on the normal functioning of groups of neurons in the primitive diencephalon. The normal cycles of sleeping and waking are evidences of the physiologic activity of this mechanism. As it would appear that energy liberated in the diencephalon is essential for the activation of all the rest of the nervous system so far as psychologic phenomena are concerned, it may be postulated that the "center" of consciousness is located in this region, and much clinical and experimental evidence supports this view. It is surely not accidental that other primitive functions of the nervous system related to the vegetative processes, instincts and emotions have been found to be dependent on structures in the basal region of the brain in close proximity to those postulated as the center of consciousness. The application of this concept of consciousness to psychiatry seems obvious, since quantitative variations of consciousness are manifested in disturbances of behavior in terms of intelligence, emotions and instinctive action.

INSTINCTS, EMOTION AND INTELLIGENCE

There has been much discussion with regard to the nature and classification of instincts, but it is generally agreed that they represent innate biologic patterns of behavior characteristic for each animal species and from which are derived the motivations of all psychologic activity. Instinctive reaction patterns of behavior tend to promote the development and welfare of the individual, the reproduction of the species and the mutual benefits derived from adjustments within the social group.

In view of the accepted structure and function relationship it must be assumed that instinctive dispositions are represented anatomically by inherited neural patterns of inconceivable complexity and are probably located in the diencephalon in proximity to centers which are concerned with the regulation of vegetative functions, emotional reactions and consciousness. We can postulate, although we cannot demonstrate, differences in the neuron patterns of the diencephalon to account for the differences in the instinctive behavior of dogs and cats; and the same conception may be applied in explanation of the different inherent human personality traits.

Emotion and affectivity are essentially components of instinctive action. In each instinctive attitude is included a characteristic emotional or affective element, and this implies that each of the neuron groups representing the different instinctive attitudes is closely connected with the neuron group representing a particular type of emotional reaction. In personality analysis, emotional expressions are most valuable clues by which to detect instinctive motivations. Dissociation of the normal relationship of instinctive motives and their appropriate emotional expressions are common in men-

tal disease and are strongly suggestive of derangements of neural patterns in the diencephalon.

Intelligence has been variously defined but in its broadest application implies the capacity to learn and profit by experience; to make observations, to remember, classify, analyze and synthesize experiences, and to utilize what has been learned to promote the success of the impelling force of instinct. By this definition the ants and bees are endowed with an elementary type of intelligence so far as they utilize the memory of their sensory observations in the performance of instinctive acts, and it seems obvious that all instinctive adaptations to environment require elementary intelligence. Instinctive movements are futile unless adapted to environment, and adaptation requires observation and memory. On the other hand, intelligence is as inert as a book on a shelf unless motivated by some instinctive interest or drive. A strong instinctive motivation with its appropriate emotion utilizes only that part of the intellectual field that applies to the situation at hand and inhibits all other sensations and thoughts. Instinct, learning and intelligence are inseparable in respect to their normal functioning, although they are to some extent localizable in different parts of the brain, and defects in behavior can to some extent be diagnosed neurologically.

Human intelligence is predominantly dependent on the cerebral cortex and association tracts. Posterior to the motor area the brain is arranged for the acquisition of knowledge. Here are located all the primary and secondary sensory areas and their subcortical connections which provide for the following activities: reception and elaboration of sensation; retention in memory and the formation of concepts; orientation, symbolization, calculation and discrimination. Anterior to the motor area the frontal lobes synthesize the information collected by the posterior areas, form judgments, develop and supervise the more complicated plans, and represent intelligence in respect to morals, ethics, wisdom and diplomacy.

HYPOTHETIC LEVELS OF PSYCHOLOGIC FUNCTION

In the neurologic analysis of motor functions it has been found useful to study the different stages or levels of motor integration and their relationship to the structural arrangement of the nervous system. The same plan may be applied in the analysis of psychologic integration, and the following outline is suggested with the full realization of its inadequacy and of the wide borderlines and extensive overlaps between the different hypothetic stages.

1. The first level, that of sensory perception, is represented anatomically by the cortical areas in which the various sensory tracts from the periphery terminate. The location of these areas is fairly well known for each type of sensation, and lesions affecting them cause impairment of sensations.

2. The second level, that of sensory integration, is concerned with the sensory memories, the retention, recognition and recall of sensations; also with discrimination in respect to similarities and differences of sensations experienced. Spatial and temporal relations and the identification of objects, symbols and colors are effected by sensory integration. The cortical areas corresponding to this level are adjacent to the primary areas for each type of sensation. Lesions affecting these areas cause impairment of sensory memory, either of recognition or recall or both; and varying types and degrees of agnosias, including the so-called sensory

aphasias, simultanagnosia, constructive apraxia, disorientation and Gerstmann's syndrome.

3. The third level may be considered to consist of the integration of various sensations related to the same experience by the process of associations or associative memory, and their translation into meanings and concepts. Recognition, discrimination and recall are here operating in the collective sense so far as the various memory areas representing the different types of sensation contribute to a common concept or idea. Anatomically, this stage of integration is represented by the subcortical association and commissural tracts connecting the various secondary cortical areas, and the interruption of these tracts causes impairment of associative memory and of the availability of concepts.

4. At the fourth level, or perhaps at an earlier stage, sensation synthesized into meaning awakens interest in the form of some instinctive disposition which determines the type of behavior which is to result. Characteristic emotions are manifested, and a general attitude of animation results which calls for action. The anatomic areas which seem to be of prime importance in relation to the instinctive motivations and emotional expressions are generally considered to be in the diencephalon.

5. The fifth stage of psychologic integration is the utilization of intelligence and all of the physical capacities of the organism for the purpose of attaining the objective demanded by some particular instinctive motivation. This process includes a more or less extensive analysis of the situation and the formation of a plan of action. All parts of the brain are utilized in this stage, although special patterns are selected which are appropriate and applicable to each situation, while others are inhibited.

6. The sixth stage of this hypothetic series is that of execution of the plan, or voluntary action. This includes voluntary motions critically directed, and modified or changed according to changing circumstances throughout the duration of the action. This process also requires constant observations, concentration of attention and a continuation of the activity of the intelligence, interest and emotions. At this level the motor areas of the brain, in particular the precentral and the premotor convolutions, are concerned, as are also the subcortical tracts leading into the motor region, and the projection tracts to the periphery. In addition to the familiar types of paralysis resulting from lesions of the motor areas and tracts, lesions of the subcortical association and commissural tracts connecting with the motor cortex give rise to ideokinetic and sympathetic apraxia.

The anatomic pathways in this series of activities would include (1) sensory end-organ and afferent pathway to primary sensory cortex, (2) primary sensory cortex to secondary (adjacent) area, (3) secondary area to other secondary areas via association tracts, (4) secondary areas for sensation to thalamus and hypothalamus, (5) basal region to adjacent vegetative and emotional centers and to widespread cortical areas, (6) convergence of impulses to the precentral (and premotor) cortex, and via projection tracts to the muscles.

The brain might be compared to a radio receiving set, the sensory end-organs representing the antennas, the afferent tracts the lead-in wires; in the brain are the amplifiers, condensers, shunt circuits, resistances, potentiometers, on-and-off switches, selectors and transformers. A and B currents are utilized, and ions are traveling

in all directions in tuned circuits. And, curiously enough, to carry the analogy a little further, the net result of much activity is frequently blatant sounds from the loud speaker.

With the foregoing conception of the successive levels of psychologic integration and of the activities implied as occurring at each level, the broader concept of "total personality" may be developed.

The neurologic concept of the total personality is complex and consists of concepts of each of the numerous factors into which personality can be divided. It provides for each factor of personality a structural basis and a physiologic activity. It postulates the inheritance by each animal of a nervous system characteristic of its species and variable with the individual, which determines definitely the capacities and the limitations of all behavior. It applies the theory of neurobiotaxis as a working hypothesis which helps to explain embryonal development as well as the processes of learning, of thought associations, of habit formation and of the "conditionings" not only of reflexes but also of emotional and instinctive activities. It recognizes the effect of endocrine hormones in modifying behavior by their selective action of the cell patterns of the nervous system. It emphasizes the importance of the instinctive drives and of the neural patterns on which they are dependent. Personality characteristics are assumed to be predetermined to a large extent for each individual by inherited arrangements in the neuronal patterns in the diencephalon which represent the instinctive trends. It considers intelligence as the expression of the faculties of observation, memory, concept formation, thought association, discrimination, calculation, reason, judgment and wisdom and it accepts the view that these faculties are exercised solely in response to instinctive motivation. It visualizes "personality" as being in a constant state of flux which depends on internal or external environmental factors, either physiologic or pathologic, and as passing through various stages, or ages, of development.

The neurologic conception of "total personality" may be compared to the mechanic's conception of the "total automobile" with regard to the performance of the machine. When it is out of order the mechanic tries to locate the trouble, but he can do this only if he knows the structure and function of each part.

CONSTITUTIONAL PSYCHOPATHIC INFERIORITY

In people as in automobiles there is much variation with regard to performance, independent of any broken or worn out parts. In machines this is manifested in design and structural material, in degrees of power, speed, durability and appearance, and in the comfort, safety, satisfaction and service they provide, to which should be added the pride or humility they incite in those to whom they belong.

Neurologically conceived, constitutional psychopathic inferiority implies personalities which fail in some important adjustment to environment largely because of "constitutional" conditions with which they are born. Theoretically, this implies variation from the average "normal" in the arrangement of the inherited structural patterns of the brain cells. Since the behavior of psychopathic inferiors does not correlate with intelligence quotients and is characterized to a large extent by emotional instability, together with over or under developed instinctive trends, it may be inferred that the cell patterns in the diencephalon representing the instinctive motivations deviate from those of the nor-

mally adapted individual and that the cortical areas are not at fault in this condition. The relative fixity of personality traits, as compared to the capacity to acquire knowledge, may be explained by the representations of innate dispositions in the primitive structures while intelligence is the function of the neopallium. The manifestations of psychopathic inferiority (and superiority) vary in a sliding scale comparable to that of intelligence. It is to be regretted that we as yet have no easily applied or practical method of estimating the personality quotient as we have the intelligence quotient.

PSYCHONEUROSIS

By common consent the psychoneuroses are termed functional conditions, and the basic cause is said to be psychogenic. The symptoms are reactions to life's failures and are not due to pathologic changes in the tissue. But to satisfy the concepts of neurology, the symptoms of the psychoneuroses require explanation, at least in theory, in terms of physical activities in the nervous system. A clue to the answer may be found in Pavlov's report of the development of neurosis in a dog under experimental conditions. Here the neurosis appeared when, after conditioned reflexes had been successfully developed, the dog was unable to discriminate between the changing signals and he failed in his adaptations. In theory the correlated physical activities may in part be conceived as follows: During the period of the successful development of conditioned reflexes, reflex patterns, or engrams, were developed by the process of neurobiotaxis. So long as the dog's adaptations were successful, no harmful emotional tension resulted. Failure to interpret correctly the signals resulted in the distressing emotions of uncertainty, confusion and frustration. May it not be conceived that distressing emotions are physically the expression of spreading and diffuse currents of polarization with cross currents which tend to disrupt the unstable engrams of recently formed conditioned reflexes, and to a less extent the more stable engrams of normal behavior? This concept may be an idle flight of fancy, but is not the neurologist, as well as other theorists, entitled to exercise imagination?

The variability of individuals with regard to the tendency to develop psychoneuroses remains to be explained. In this respect the innate structural arrangement of the nervous system is a factor, as in the case of psychopathic inferiority; many writers consider the neuroses to be in a large extent the expression of inferiority. Another factor to be considered is that of hypoplasia of the nervous tissue, comparable to hypoplasia in various other tissues. May not neurasthenia be in part the expression of such hypoplasia?

PSYCHOSES

In the field of the psychoses the accumulations of biologic science have promoted the correlations of mental symptoms and changes of personality with physical changes in the brain in terms of neuropathology and biochemistry, including hormonal reactions and electrical polarizations. In the classification of mental diseases only two important groups still remain in the list of the so-called functional psychoses; viz., manic-depressive and schizophrenia. These still defy analysis with regard to the basic etiologic factors or the physical conditions in the brain cells which are manifested in symptoms. In both of these groups the abnormal behavior indicates disturbances in the patterns of instinctive motivation and emotion rather than of intel-

ligence. The ups and downs of the cyclothymics may be conceived to correlate with corresponding degrees of cellular activity and polarization in the diencephalon, without disarrangement of the patterns as such, while in schizophrenia the symptoms of dissociation of the instincts, emotions and intelligence suggests a disarrangement of the neuron patterns and inharmonious polarizations in the basal region in which instinctive motivations arise. It seems probable that, to a certain degree, the same factors are at work in these two types of psychoses that are recognized in the etiology of the psychoneuroses, viz., the secondary effects of frustrations; but this theory is inadequate to explain these psychoses.

The neurologic approach to the problems of psychiatry is physiologically analytic and diagnostic, not therapeutic, and it can never replace psychologic analysis; but it contributes to the science of psychiatry in that it broadens the concepts of the relations of the structures of the nervous system with the manifestations of behavior.

In conclusion it may be stated that neurology has made its share of contributions to the science of psychiatry, and it should be emphasized that the neurologic aspects of psychiatry must be correlated with the psychologic aspects to attain the best available conception of human personality and its deviations from normality.

ACUTE GLOMERULONEPHRITIS WITH SPECIAL REFERENCE TO THE COURSE AND PROGNOSIS

A STUDY OF 150 CASES

FRANCIS D. MURPHY, M.D.

AND

J. W. RASTETTER, M.D.

MILWAUKEE

Although there is extensive literature on the subject of acute nephritis, some of its practical aspects appear to escape recognition or to be regarded too lightly. If the classic textbook picture of hematuria, hypertension and edema is considered essential for a diagnosis of acute nephritis, then many milder forms will pass unrecognized, and not until years later, when chronic nephritis has set in, will the true significance of the mild early episode become apparent.

While the opinion is not unanimous that chronic glomerulonephritis is always a consequence of an acute form, in many cases the chronic form is observed to evolve from an acute attack, either immediately by direct continuity or after a succession of relapses and remissions during which the patient is apparently well. The absence of a history of an acute attack in many cases of chronic nephritis may be explained to some extent by the fact that during the acute phase the classic picture of hematuria, edema and hypertension was lacking. A stumbling block in the proper appraisal of acute nephritis has been the limited view taken of the cause and pathogenesis by many observers. Formerly, hematuria, edema and hypertension were

From the Department of Medicine, Marquette University School of Medicine, and the Medical Clinic, Milwaukee County General Hospital.
Read before the Section on Practice of Medicine at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

required for a diagnosis, but within recent times the concept of acute nephritis has changed. It has been emphasized that mild subclinical forms may exist, pass undiagnosed and untreated, and progress insidiously into the chronic stage before it is realized that the kidneys have become irreparably damaged. This concept has been confirmed and extended recently by the histologic examinations of Bell,¹ who stated that there are innumerable transitions between subclinical glo-

TABLE 1.—Comparison of Ages with Outcome in 150 Cases of Acute Glomerulonephritis

merulitis and clinical acute nephritis and that fundamentally the same type of reaction occurs in the two forms, the difference existing only in the intensity of the disease. This better understanding of the clinical and histologic features of acute nephritis removes one of the main obstacles which has retarded progress in this field.

Our presentation comprises a study of 150 cases of acute glomerulonephritis observed in the acute stage and followed for periods varying from two to fourteen years. We have had the opportunity of observing some patients in the acute stage of nephritis who have passed through the transitional stage into the chronic phase and have seen renal insufficiency gradually develop and the patients die of uremia or of some other complication of chronic nephritis. The purpose of this report is to emphasize the following aspects of the problem of acute nephritis: (a) The importance of a number of diseases which may precipitate acute nephritis but are not generally considered as common etiologic factors. (b) The significance of early recognition of the signs and symptoms of milder forms of the disease. (c) The necessity of careful observation of patients in the quiescent period that often immediately follows the acute phase. In this period, which is called here the transitional stage, the sequelae, both immediate and remote, may be recognized and the patient may be protected from future ill consequences by judicious treatment. (d) The value of measures which aid in determining whether or not the renal lesion has completely healed. The vital importance of adequate treatment cannot be overestimated, for the patient who appears clinically cured may have some residual inflammation which may progress unless it is treated effectively.

CLINICAL DATA

The criteria for the diagnosis did not include definite retention of nitrogenous substances, hypertension, edema or hematuria. A patient who had albumin, red blood cells, casts and pus cells in the urine for a week or more was considered to have acute nephritis. In table 1 the age incidence is compared with the outcome. Of the 150 patients 105, or 70 per cent, were

under 30 years of age. Of this number fifty-two, or 39.52 per cent, recovered; the disease of 41, or 39.04 per cent, became chronic, and twelve, or 11.43 per cent, died. Of the forty-five patients over 30 years of age twenty-two, or 48.88 per cent, recovered; the disease of twelve, or 26.66 per cent, became chronic, and eleven, or 24.44 per cent, died. This table emphasizes that acute nephritis in an older group is probably more serious and has a higher mortality rate than in a younger group. The patients were predominantly under 30 years of age, but only twenty-six, or 17.33 per cent, of the total were under the age of 10.

The age and sex incidence is given in table 2. In the age group below 10 years the boys outnumbered the girls almost 6 to 1, but this ratio did not prevail throughout the series. Of the total number of patients 102 were males and forty-eight were females, showing a ratio of about 2 to 1. Table 3 shows the relation of the age and sex to the progress of the disease. Of the seventy-four patients who recovered, or 49.33 per cent of the total series, fifty-two, or 70.27 per cent, were males and averaged 23.23 years of age. The number of females in this group was smaller, twenty-two, or 29.73 per cent, yet the average age was practically the same. In the group of patients who died, males predominated almost 3 to 1 and the average age of both sexes was higher than that of the patients who recovered or in whom the condition became chronic. Twenty-three, or 15.33 per cent, of the patients died; seventeen, or 73.91 per cent, were males and 6, or 26.09 per cent, were females. The average age of the males was 30.58 years and of the females 20.33 years.

In table 4 the antecedent diseases in 150 cases of acute nephritis are given. Formerly it was thought that severe infections such as scarlet fever and septic sore throat were the chief forerunners of acute nephritis, but now it is agreed that almost any infectious disease may precede the onset of renal inflammation. The commonest antecedent disorders in our series were

diseases caused by streptococcal infections of the throat and upper part of the respiratory tract. Many authors² have stressed the importance of this relationship. The point of emphasis is that infections of the upper part of the respiratory tract which are often not thought of seriously may be forerunners of acute nephritis.

Nephritis followed such infections in ninety-nine, or 66 per cent, of our 150 cases. In 67.6 per cent of seventy-eight cases studied by Winkenwerder, McLeod

cause of acute nephritis. When it becomes more widely recognized that there is a tendency for nephritis to develop in patients with simple infections of the upper part of the respiratory tract and other pyogenic infections, repeated urinalyses will reveal many more cases of early acute nephritis.

Twenty-three of our patients with acute nephritis died, as seen in table 5, but only twelve of these, or 52.17 per cent, died of acute glomerulonephritis or uremia. Pneumonia, septicemia, burns, erysipelas and heart failure caused death in the remaining eleven cases. It is often difficult to determine the part played by nephritis in causing death and the part contributed by associated diseases. It has been our practice to consider nephritis as the primary cause of death unless some other obvious cause is found. When our death rate of 15.33 per cent is compared with that reported in studies of similar series (Richter⁹ and McPhee and

CLINICAL SYNDROMES

In acute nephritis, as in the chronic form, there are five clinical syndromes: (a) the urinary syndrome, (b) hypertension, (c) edema, (d) retention of nitrogenous products in the blood and (e) uremia. These syndromes need not all be present at one time; they are variable and transitory. One may develop and dominate the clinical picture for a period and then disappear temporarily or permanently. The clinical syndromes which occurred in the 150 cases under discussion are analyzed and their relation to the progress is shown in table 6.

(a) *The Urinary Syndrome.*—The urinary syndrome is the most important because it is always present, is the most accessible and is the least likely to be misinterpreted. The diagnosis of acute nephritis was not made in the absence of albuminuria in any case. Albuminuria must be considered evidence of nephritis unless it is proved otherwise. In many of

blood cells, pus cells and granular casts were present. In some cases it was difficult to decide whether the urinary changes only signified benign febrile albuminuria or were identification marks of a mild but genuine acute nephritis.

In our cases the albumin in the urine varied from a few grams to as much as 20 Gm. a day, but the quantity seemed to have little effect on the outcome. According to Bell¹ the amount of albumin does not correspond to the degree of glomerular damage because the most severely damaged glomeruli have closed capillaries and do not transmit albumin.

The term hemorrhagic nephritis is often used interchangeably with glomerulonephritis because in some cases of acute glomerulonephritis there is gross

hematuria. In this series gross hematuria was present in forty-eight, or 32 per cent, of the cases; in the remainder red blood cells were found on microscopic examination of the urinary sediment.

(b) *Hypertension and the Heart*.—Hypertension was formerly looked on as a constant feature in acute nephritis. In table 6 the incidence of hypertension is given in relation to the ultimate outcome of the disease. When hypertension was present in our cases the systolic blood pressure ranged between 140 and 180 mm. and the diastolic between 90 and 110 mm. Hypertension may be absent throughout the course of the disease and yet chronic glomerulonephritis may develop; on the other hand, we have studied patients with excessive hypertension, prominent changes in the fundus oculi and hypertensive encephalopathy who have recovered completely.

The seriousness of acute nephritis depends at times not so much on the renal inflammation as on disturbances in the function of the heart. Myocardial insufficiency may develop, and there may be either frank heart failure or milder symptoms, such as palpitation, tachycardia, pallor, enlargement or pulmonary congestion. The excessive burden of hypertension cannot in most cases be held responsible for cardiac embarrassment; many authors have attributed it to a systemic vascular disorder due to the same agent that causes the acute nephritis. In table 5 it is shown that one of our patients died of heart failure, but this does not reflect the importance of cardiac insufficiency in the series, for in other cases myocardial damage was a prominent factor in the unfavorable outcome although it was not considered the primary cause of death. The role of myocardial insufficiency in acute nephritis varies according to different authors. In Cecil's¹¹ textbook it is stated that the heart as a rule is not damaged in acute nephritis. Levy¹² and Murphy, Grill and Moxon¹³ discussed cases of acute nephritis in which heart failure occurred without hypertension. More recently Master, Jaffe and Dack¹⁴ found cardiac insufficiency to be common in a series of twenty-four cases and at times to be severe enough to cause death. Rubin and Rapoport¹⁵ studied the cardiac complications of acute hemorrhagic nephritis and concluded that the involvement of the heart is caused by a combination of hypertension and myocardial damage from infection. Hypertension was present in all their cases. They examined fifty-five children and found severe myocardial damage in fourteen and signs of frank failure in twelve.

(c) *Edema*.—Edema developed in eighty-six, or 57.33 per cent, of our 100 cases, but in no case was it a serious complication. As seen in table 6, there was no relationship between the degree of edema and the course of the disease. Puffiness about the eyes, slight ascites and swollen ankles were frequently observed, but as a rule when generalized anasarca developed the disease had passed from the acute stage of nephritis into the subacute or chronic form. From determinations of the plasma protein level it was found

that the edema of acute nephritis in most instances preceded any pronounced changes in the plasma protein level, and there appeared to be no causal relationship between the two. In some cases of severe acute nephritis with prominent edema, the plasma protein level was found to sink gradually as the disease progressed. There may be three kinds of edema in acute nephritis,

TABLE 6.—*Syndromes in 150 Cases of Acute Glomerulonephritis*

Syndrome	Patient Recovered		Condition Became Chronic		Patient Died

the nephritic, the nephrotic and the cardiac, and it is the belief of Page,¹⁶ Rennie¹⁷ and Peters and Van Slyke¹⁸ that in the earlier periods nephritic edema is caused by increased capillary permeability.

(d) *Nitrogen Retention*.—In sixty-six, or 44.44 per cent, of our 150 cases there was some degree of nitrogen retention. The level of blood urea nitrogen may be normal during the early periods of the disease and then rise suddenly after the first seven or eight days. Oliguria or even anuria is likely to be present in early acute glomerulonephritis, and, since the output of urea nitrogen is dependent on the amount of urine excreted, the nonprotein nitrogen level of the blood may rise swiftly at this time. After several days, however, diuresis usually sets in, and this is followed by a prompt reduction of the blood nitrogen. A gradual rise in nonprotein nitrogen over a period of three weeks, as shown by repeated examinations, is a grave prognostic sign.

(e) *Uremia*.—As seen in table 6, there were ten cases or 6.67 per cent of the total series of 150 cases, in which there was genuine uremia. Uremia is a difficult syndrome to evaluate because the term is often used to describe both the genuine and the convulsive, or false, form of uremia. Convulsive uremia is identified by headache, visual disturbances and choked disks. It

is practically always associated with, and is probably caused by, hypertension; nitrogen retention and anuria are unrelated to its development. In sharp contrast to the convulsive form is genuine or true uremia, which is a manifestation of renal insufficiency and is unrelated to hypertension.

COURSE

Acute nephritis follows one of several courses: The patient may die in the acute attack, subacute or chronic nephritis may develop, complete healing may occur or slight albuminuria with no formed elements in the urinary sediment may persist for years. The last-mentioned type of development was pointed out by Addis¹⁹ as an example of healing with defect. Most patients with acute nephritis recover within six weeks. In some cases healing appears to be complete when in reality the renal inflammation has only become less intense, and the patient is dismissed from further observation. He may be oblivious of the fact that the kidneys are damaged until years later, when evidence of permanent injury appears. It is therefore most important to determine whether or not the renal lesion has healed before dismissing a nephritic patient from treatment. After the severity of the acute phase has passed there is a period of transition during which recovery may occur or the disease may become chronic. Routine tests, such as the phenolsulfonphthalein test, analysis of the blood for retained nitrogen and determination of the blood pressure, may lead one to believe that the renal lesion is healing satisfactorily but more exhaustive examination may prove that this is not the case.

No one test has been found a reliable prognostic index in every case, but the result obtained from a combination of several measures may be used as a fairly accurate guide. A study of the dilution-concentration test of Volhard or one of its modifications, the blood urea clearance test, and determination of the sedimentation rate of the erythrocytes have been particularly helpful. The quantitative methods of urinalysis described by Addis²⁰ are of diagnostic and prognostic value, especially in determining whether the renal lesion is still active or is becoming latent. The blood urea clearance test as described by Möller, McIntosh and Van Slyke²¹ was particularly helpful in the study of our cases. As reported previously,¹⁴ the urea clearance test repeated over a period of weeks will show whether the trend is toward healing or chronicity. Cullen, Nelson and Holmes²² made a study of the urea clearance of children recovering from acute nephritis for the purpose of detecting residual renal damage and

found the test to be of value in determining the extent of the renal involvement during the acute stage of nephritis. The dilution-concentration test at times appears to be a more valuable aid than the other tests; yet an accurate prognosis depends not on any one test but on a composite picture of all tests. Alving and Van Slyke²³ have compared the prognostic significance

of the urea clearance and dilution-concentration tests. Determination of the sedimentation rate of the erythrocytes has proved to be of distinct aid in prognosis. This, like the other tests, is not an infallible guide, since some patients with active lesions have a normal sedimentation rate. Within recent years Cutler²⁴ has emphasized the importance of using a standard method in performing the test, and he has pointed out its limitations in the field of internal medicine. Tables 7, 8 and 9 show variations observed in the sedimentation rate of three patients with acute nephritis; one recovered, another died and in the third the condition

became chronic. We have found that, taken with the other tests, the determination of the sedimentation rate is a helpful prognostic aid. However, repeated tests at frequent intervals are necessary, since a single determination may lead to false impressions. When the renal lesion is becoming quiescent the rate falls, and when the lesion is progressing it is more rapid. The fact that the test is simple and easy to perform adds to its practical value.

COMMENT

The recent publication of Baehr²⁵ emphasizes that there is no unanimity of opinion regarding the significance of the so-called milder forms of acute glomerulonephritis. He expressed the opinion that an early diagnosis can be made positively only if, in addition to the urinary abnormalities, there are other clinical evidences of vascular disturbances. Our observations convince us that there are mild forms of acute nephritis characterized by albuminuria, microscopic hematuria and casts which progress eventually into chronic glomerulonephritis without developing into the classic picture of gross hematuria, hypertension and edema. The fact that so many patients with chronic nephritis have no history of an acute attack may indicate that the first stage was so mild as to be unrecognized and that nephritis was not suspected until urinary abnormalities were discovered some time later. Whether chronic glomerulonephritis always evolves from the acute form is an unsettled question. Volhard² said that in every case chronic nephritis is the result of an unhealed acute form, but Aldrich²⁶ found no instances of chronic nephritis following an acute attack in 129 cases studied from one to twelve years. Aldrich and Boyle²⁷ said that in some cases glomerulonephritis develops slowly and insidiously without having had an acute stage. In a series of 186 cases of chronic nephritis, Nye²⁸ found

only two in which there was a history of acute nephritis or hematuria in any period of childhood. Although some patients with chronic nephritis have had renal inflammation earlier in life, Horder²⁹ stated that others are known to have been free from acute nephritis. Chronic nephritis is not a progressive disease varying in severity at different periods, according to Emerson,³⁰ but is rather a succession of distinct acute attacks distributed over a period of years, each adding to the permanent injury of the kidney as a whole.

In the opinion of such observers as Fishberg,² Bell and Hartzell,⁸ Mosenthal,³¹ Longcope² and Volhard² it is uncommon for acute nephritis to progress directly into the chronic stage. There are many intermediate phases that bridge the gap between the acute and the chronic. Occasionally, however, an acute attack is seen to pass directly into the chronic form. Roper³² said "A silent period may ensue for years, during which time there are no symptoms," but he added that in other cases there is no silent period and the acute symptoms merge directly into chronicity. Addis¹⁹ expressed the opinion that the patient with acute nephritis may pass into a latent stage which may persist for a long time.

Most authors accept the idea that unhealed acute nephritis may pass into a subacute form, but there are some who do not agree that a long period of latency or quiescence may endure in the kidney. Boyd,³³ Elwyn³⁴ and Fishberg² said that in order for nephritis to become chronic there must be some extrarenal infection which subjects the kidney to repeated infections or rather, repeated intoxications.

A point which deserves consideration is whether or not the course of acute nephritis can be influenced by the removal of septic foci. Platt³⁵ and Alport³⁶ expressed the opinion that there is evidence that this procedure exerts a favorable influence. The removal of the source of infection tends to slow down the progress of the disease, and the more promptly such foci are attacked the better for the patient. Guild,² from a study of thirty-four patients over a period of years, concluded that many patients return entirely to normal in spite of neglect of foci of infection after the attack of nephritis. Patients who continue to show red blood cells, albumin and casts in the urine after several months of rest in bed are discussed by Osman.³⁷ Their ultimate fate is unsatisfactory. He undertook to determine the value of tonsillectomy in a group of patients with unresolved acute nephritis and found that only one of eight consecutive patients was benefited.

It is of practical importance to determine to what degree the active inflammatory lesion is dependent on an extrarenal focus of infection and whether or not the course of acute nephritis can be influenced by such a focus. As may be seen from the foregoing discussion

the persistence of active inflammation in the kidney appears to depend on some focus of infection, either the one which originally set the disease in motion or a subsidiary extrarenal disturbance. The point to be emphasized is that treatment must be directed so as to safeguard the patient from additional infections. One requirement is that the nephritis be completely cured, if possible, before the patient is dismissed from treatment. When a patient recovers from acute nephritis the chance of a new attack is remote, but such an attack may occur. On the other hand, the person who has an unhealed renal lesion has a vulnerable kidney, and infection of the upper part of the respiratory tract, tonsillitis or exposure to cold may provoke a relapse.

Our observations have led us to conclude that many persons in whom chronic nephritis develops even years after an acute attack have had a persistent continuous inflammation in the kidney. The course during the years of transition may be characterized by periods of exacerbation due to repeated attacks of infection in the upper part of the respiratory tract and by remissions, which often occur in the summer, when such infections are not prevalent. We believe that by the careful study of our patients in the intermediate period we have been able to show that this is the case.

TREATMENT

The better understanding of the significance of milder grades of acute nephritis has been reflected in more effective treatment. The onset of acute nephritis may be abrupt and the course stormy, terminating either fatally or favorably in a few weeks' time, or it may be insidious and follow a long slow course. Consequently therapeutic measures vary. It must be remembered that, however mild the attack, every patient with an acute renal inflammation is a candidate for chronic nephritis, and every effort must be bent toward the complete healing of the renal lesion. The treatment used in the classic case of acute glomerulonephritis with profound renal insufficiency is well known, while the problem of the patient with a milder grade of acute nephritis and of the person in the so-called transitional period is less well understood. This problem will be discussed briefly.

The fundamental principle in treatment is to obtain as complete a rest for the inflamed kidney as possible. Therefore the patient should be put to bed and kept there until the disease has healed or become chronic. If albumin, red blood cells and casts persist in the urine after three months and other evidences of inflammation, such as hypertension, reduced urea clearance, impaired concentration ability or rapid sedimentation rate, are present, it may be assumed that chronic nephritis has developed and further rest in bed will be of no avail.

The removal of foci of infection is useful and sometimes an immediate therapeutic necessity. Diseased tonsils or sinuses, apical abscesses and foci of infection anywhere should be treated to prevent further irritation. There is a considerable difference of opinion as to the best time to remove foci of infection. We believe that this depends on the severity of the nephritis. Surgical procedures are unwise during the early stages of acute nephritis if there is evidence of renal insufficiency, because there is danger of aggravating the condition. When the severity of the initial stage is over, operative procedures may be used most advantageously.

Keutman and McCann³⁸ have shown that a high protein diet does not retard recovery from acute glomerulonephritis. However, it is not necessary to give a patient more than a minimal amount of protein, from 0.6 to 0.8 Gm. per kilogram of body weight, during the acute stage. Since the course of the disease and the duration of the acute phase are usually short, the intake of protein and calories may be disregarded for several days. Such observers as Volhard,² Fishberg² and Stone³⁹ have said that the rigid restriction of salt, food (especially proteins) and fluids (except from 400 to 600 cc. of fruit juices) is advisable for three or four days. After this period the quantity of fluid and food is gradually increased as required.

The amount of fluid that should be given to a patient with acute nephritis varies according to the degree of renal insufficiency. When the kidney is unable to secrete urine there is little object in giving fluid, yet some authorities believe that large quantities of fluid promote diuresis and eliminate toxins. The following factors should provide guidance for the administration of fluids. If there is oliguria or anuria with a rising level of nonprotein nitrogen, sufficient fluids should be given by mouth or by vein to promote diuresis if possible. Since the output of the toxic substances is dependent to a large degree on the secretion of urine, diuresis is desired. If there are hypertension and edema of the brain with increased pressure of the cerebral spinal fluid or evidence of myocardial weakness, fluids must not be forced, for they may aggravate these complications. The presence of edema is not a serious matter and should not be the deciding factor for or against the administration of fluid. The kind of fluids to be given must be decided to suit the individual case. If there has been vomiting, dehydration, oliguria or anuria, 10 per cent dextrose solution with physiologic solution of sodium chloride is necessary in order to maintain the electrolyte pattern of the tissue fluids. If diuresis is all that is aimed at, dextrose solution may be given daily. When there is edema of the brain with increased pressure of the cerebral spinal fluid and threatening convulsions, from 100 to 200 cc. of 50 per cent sucrose or dextrose solution given intravenously may be effective in reducing the pressure of the cerebral spinal fluid.

Since anemia is often a problem met with in cases of acute nephritis, large doses of iron and ammonium citrate three or four times a day are a favorite prescription. Efforts should be made to build up the patient's resistance. Proper amounts of food rich in vitamins may be helpful. It is believed by some observers that vitamins A and D especially are valuable in protecting the patient from further infections. Diuretics are not well borne in any phase of acute nephritis, and it is unwise to use them unless there is edema of cardiac origin; in this case digitalis, theobromine or small doses of theobromine with sodium salicylate may be effective.

SUMMARY

1. Numerous diseases precede acute nephritis and may have an etiologic role, and there is a lack of correspondence between the seriousness of the antecedent disease and the severity, duration and termination of the nephritis.

2. The classic textbook picture of acute nephritis is often lacking, and mild forms occur which are characterized by the urinary syndrome alone. Such mild forms are frequently overlooked, and evidence of renal damage is not observed until the disease has progressed into the chronic stage and renal insufficiency has set in.

3. If success in the treatment of acute nephritis is to be achieved, prompt recognition of the early and mild types is of the first importance. After the manifest symptoms of acute nephritis have subsided there is a period called the transitional stage, in which the renal lesion may heal completely or the disease may progress into the subacute or chronic form. It is necessary to determine whether or not healing has occurred. No one test will give this information, and a combination of diagnostic aids should be employed.

536 West Wisconsin Avenue.

ABSTRACT OF DISCUSSION

DR. THOMAS ADDIS, San Francisco: The observation by Drs. Murphy and Rastetter in Milwaukee that half of their patients completely recover after passing through the initial stage of glomerular nephritis is in exact agreement with our experience in San Francisco. That is important because disagreement on this point has raised the question as to whether there may not be geographic differences in this disease analogous to the differences in the behavior of rheumatic disease on the Atlantic and Pacific Coasts. It is known now that there is at least no evidence of difference between Midwest and Far West. But neither Milwaukee nor San Francisco can tell how many of all the people who have glomerular nephritis recover. Everywhere an undetermined proportion of these people, particularly those with mild forms of the disease, escape detection and are seen by nobody. I do not believe that the disease is maintained by foci of infection or that transient generalized toxic states induced by bacterial or virus infections are often determining factors in the outcome. In this disease the end is determined by the beginning and that is why I agree with Drs. Murphy and Rastetter that the treatment of the initial stage is all important. If we follow the traditional methods we sweat, purge and starve these patients and interfere with their natural desires with respect to water by giving them either more or less than they want. But that tradition is already passing and it has begun to be recognized that the only rational therapeutics is to put the patient under conditions that induce a state of relative rest for the kidney. One thinks of the blue swollen kidneys with a circulation impeded by endothelial glomerular proliferation and inflammatory stasis; the patient must have mechanical rest and we put him to bed. But beyond that one judges, by analogy, that during that first crucial week or two the greatest possible decrease in the specific work of the kidney is needed. That means a minimal nitrogen excretion and that can be obtained only by a diet adequate in calories but with as little protein as possible. Drs. Murphy and Rastetter will, I am sure, agree that there is something even more important than the treatment of the initial stage. There is a real hope of prevention because in this disease there are a number of factors all essential for the initiation of the process. It is not only the streptococcus plus some constitutional susceptibility, for I have now seen four pairs of identical twins, that is to say, people with identical constitutional susceptibilities and after streptococcal infections one of each pair comes down with glomerular nephritis, the other escaping. Is there some immunologic peculiarity without which no scarlet fever patient will have nephritis?

DR. FRANCIS D. MURPHY, Milwaukee: I was happy to have my ideas confirmed by Dr. Addis, who has paid so much attention to this type of problem. I believe that, as Dr. Addis pointed out, when the patient is in the chronic stage of nephritis, so little can be done in a general way that the time to treat these patients vigorously is in the earlier stages when a great deal can be done to eradicate the inflammatory lesion entirely.

UTERINE MYOMECTOMY

ANALYSIS OF INDICATIONS AND RESULTS
IN 523 CASES

VIRGIL S. COUNSELLER, M.D.

AND

ROBERT E. BEDARD, M.D.

Fellow in Surgery, the Mayo Foundation

ROCHESTER, MINN.

In a Hunterian lecture delivered before the Royal College of Surgeons of England, Victor Bonney¹ said: "Since cure without deformity or loss of function must ever be surgery's highest ideal the general proposition that myomectomy is a greater surgical achievement than hysterectomy is incontestable." This statement is particularly true when dealing with myomas during the child-bearing period, whatever this period may be. This designated time is arbitrarily set by some gynecologists as terminating about at the age of 40 years but, obviously, the function exists until after the menopause. The psychologic effect produced by the loss of the power to conceive is too frequently disregarded in the management of uterine myomas. It is, of course, much easier to perform a subtotal hysterectomy but the technical difficulties of myomectomy are minimized by good results obtained among young women to whom the procedure is applicable. The decision as to when it is applicable is the individual responsibility of the surgeon, who must be guided by the age, number of tumors present, the patient's desire for subsequent children, associated pathologic conditions of the adnexa, the possibility of recurrences and the ability of maintaining a serviceable organ.

Myomectomy as a surgical procedure had its origin first in the removal of single pedunculated myomas, and later it became customary to enucleate single myomas from the body of the uterus itself. The good results which attended these procedures have been extended in recent decades by such men as W. J. Mayo,² Clark and Norris,³ Bonney, Giles,⁴ Labey,⁵ Murray⁶ and others, to the point where multiple myomas of all sizes and positions have been removed with conservation of the uterus as a functioning organ. Myomectomy is not regarded favorably by the profession in general except by those men who are not only technically adept in pelvic surgery but also have in mind the effects on the organism of the loss of the physiologic functions of the reproductive mechanism.

The risk of the operation is looked on by some as excessive in comparison with hysterectomy but, from reports in the literature made by capable gynecologists, the risk is essentially the same as for subtotal hysterectomy; namely, from 1 to 2 per cent. The convalescence, especially if multiple tumors are removed, may be more febrile than that following hysterectomy; the febrile reaction ensues from the absorption of blood from the uterus or from the pelvic peritoneum, which

is in no way detrimental. Convalescence following removal of pedunculated tumors is virtually uneventful.

The percentage of recurrence is a variable factor and depends on the completeness of removal of all small seedling tumors. Some are of the opinion that it is not necessary, in the presence of multiple large and small tumors, to remove all of the smallest ones. Nevertheless, if meticulous care is exercised in removing the smallest leiomyoma, the incidence of recurrence should be proportionally reduced. However, when operating in pregnancy for the removal of an obstructing or degenerating myoma, it would not be prudent to remove other insignificant myomas at that particular time; also, as in our own cases, myomectomy occasionally is performed as a secondary procedure incident to an appendectomy or ruptured ectopic pregnancy, excision of endometrial implants, presacral resection and ovarian cysts, in which cases smaller tumors within the myometrium might be overlooked.

We wish to present our observations in 523 cases in which abdominal myomectomies for uterine myomas were performed at the Mayo Clinic between 1925 and 1934 inclusive. During this decade about 3,400 hysterectomies were performed for leiomyoma of the uterus,

TABLE 1.—Age Distribution in Myomectomy (523 Cases), 1925-1934

Youngest.....	18 years	

which gives a ratio of about six hysterectomies to each myomectomy; or, myomectomy was performed in about 14 per cent of the total number of cases in which operation was performed for leiomyomas during this period.

It is often stated in discussions of this subject that the late thirties should be the upper limit for patients who are to be subjected to myomectomy. Therefore, for purposes of clarity we have divided our series into groups: those less than 40 years of age and those 40 years of age or older. Of the 523 patients, 409, or 78 per cent, were less than 40 years of age and 114, or 22 per cent, were 40 years of age or older; of the latter group, the presence of leiomyomas was of secondary importance to other indications for operation in 55 per cent of cases.

AGE INCIDENCE

The largest number of myomectomies performed was 330, or 63.3 per cent, in the fourth decade. The oldest patient was 69 years of age and the youngest 18. The average age was 36.7 years. Only thirty-eight patients, or 7.3 per cent, were actually beyond the reproductive period (table 1).

MENSTRUAL HISTORY

The menstrual disturbances conform to the same general rule among those patients treated by myomectomy as for leiomyomas in general. We found that 199 patients, or 38 per cent, had normal menstrual periods. This was particularly true among those patients who had only large pedunculated tumors and in cases in which the myomas were small and usually of secondary importance. Two hundred and sixty-nine patients, or 51.4 per cent, had abnormal periods; that is, 137, or

50.9 per cent, had chiefly menorrhagia and/or metrorrhagia, whereas in 128 cases, or 47.6 per cent, the chief disturbance was dysmenorrhea (table 2). This incidence of pain is somewhat surprising and might lead to the diagnosis of adenomyoma or endometriosis.

DESCRIPTION OF TUMOR

The tumors were studied with regard to whether they were single or multiple and with regard to size. We divided them into those 4 cm. or less in diameter and those over 4 cm. in diameter. The importance of the tumor was then noted; that is, whether it was of primary or of secondary consideration.

The occurrence of leiomyomas is almost evenly divided between single and multiple tumors. It is obvious from this that the presence of a single leiomyoma was not the sole indication for myomectomy.

Small tumors are somewhat in excess but 227, or 43.4 per cent, were classed as large tumors or exceeded 4 cm. in diameter (table 3). The excess of tumors less than 4 cm. in diameter is explained on the basis of the primary or secondary importance of the tumor; that is, many of the small tumors whether single or multiple were removed as a secondary procedure in conjunction with other pelvic operations. There were, therefore, 229, or 43.8 per cent, classed as of secondary importance and, in the majority of these, the tumors were less than 4 cm. in diameter. The largest myoma measured 27 cm. and the smallest 2 mm., and the largest number of myomectomies in any one case was fifteen.

One of us (Counsellor) has called attention to the importance of the situation of the myoma in relation to the uterus in selecting the type of surgical treatment in the management of uterine myomas. This is of particular importance in the consideration of myomectomy. In this connection, myomectomy holds a favorable position, because the majority of myomas are situated in the body of the uterus, usually on the anterior or the posterior wall. They are usually designated as subserous, interstitial or submucous according to whether they are under the peritoneum, embedded in the wall of the uterus or under the mucosa. It was previously considered a greater risk to penetrate the uterine cavity than not to do so in performing a myomectomy but,

if myomas are situated in the submucous position, it is frequently of distinct advantage to be able to control bleeding and to locate additional small tumors similarly placed which, if not removed, might reasonably produce an early recurrence of symptoms. Opening the uterine cavity in performing an abdominal myomectomy is distinctly contraindicated wherever there is a pedunculated submucous leiomyoma which has become partially extruded through the cervix because, in the majority of such cases, there is an associated endometritis.

It was not possible to give the specific site with respect to the uterus in this series because this information was not contained in a sufficient number of the operative records to be of value; however, 473, or 90.4

per cent, were situated in the fundus exclusive of thirty-two, or 6.1 per cent, which were situated in the horn of the uterus and a few each in the broad and round ligaments and in the cervix. A great many of the tumors were on the anterior wall, interfering with distention of the bladder, but in only eleven instances, or 2.2 per cent, was there any evidence of important vesical dysfunction.

In this connection, it is important to state that when a myoma is encountered on the anterior surface of the uterus and the wall of the bladder is attached to the

myoma, it is occasionally better operative technic to resect that segment of the bladder which is attached to the tumor rather than produce any excessive interference with the blood supply of that segment of the bladder because, when the blood supply of any segment of the bladder is disturbed, a secondary and persistent interstitial cystitis may be a complicating sequela.

When myomas are situated in a horn of the uterus, as obtained in 6.1 per cent of our cases, the function of the fallopian tube on that side may be destroyed or at least seriously interfered with. In cases in which this situation is obvious, it is usually safer to remove the tube and, as a protective measure, to utilize the round ligament in covering the defect in the uterus. Also myomas which extend from the lateral wall toward the broad ligaments are usually pedunculated and their removal is usually complicated by the position of the ureter and the uterine vessels. In enucleating such tumors we have found it of distinct advantage to open the anterior sheath of the broad ligament near the pedicle of the tumor and visualize these structures. The ureter usually will be situated posteriorly and can be seen as the tumor is rotated anteriorly, and then the ureter can be carefully protected. If the ureter is anterior, it can be mobilized and retracted out of harm's way with gauze tape.

When the uterine arteries and veins are intimately attached to the pedicle, these structures can be safely ligated on that side without any subsequent complications, provided the blood supply on the opposite side is intact.

If tumors are situated in the posterior wall of the uterus and are not pedunculated, it is much wiser, as Murray points out, to enucleate these tumors through an incision in the anterior wall directly through the uterine cavity so as to obviate the necessity of an incision on the posterior wall to which the bowel might subsequently become adherent and produce intestinal obstruction. Through such a maneuver, the myometrium is more favorably conserved. It should be stated, therefore, for the same reason that whenever myomectomy is performed it should be through the anterior surface of the uterus or through the anterior sheath of the broad ligament. In some situations this is not feasible, and then it is extremely important to have the surface as

smooth as possible. We feel, however, that the incidence of intestinal obstruction following myomectomy has been overestimated and is of less importance if the omentum is utilized to the best advantage at the conclusion of the operation.

ASSOCIATED OVARIAN DISEASE

In less than half of all the cases, 47.4 per cent, there was positive evidence of ovarian disease other than malignancy. In 19.7 per cent all evidence of ovarian disease was lacking, whereas in 32.9 per cent the records did not contain any statement to specify the presence or absence of it; but this is presumptive evidence that ovarian disease did not exist, at least to the extent of requiring treatment. If one permits such an interpretation concerning the latter group, 52.6 per cent of the cases were not associated with ovarian disease. This would conform to the usually accepted fact that ovarian disease is associated with uterine myomas in approximately 50 per cent of the cases. If myomectomy is the procedure of choice, conservative operations on the adnexa are decidedly indicated especially if the two adnexa are similarly involved. A unilateral salpingo-oophorectomy is often necessary but still is considered a conservative operation. We have encountered patients who had repeated pregnancies occur subsequent to the removal of one fallopian tube and the opposite ovary. The same experience has followed the removal of one tube and bilateral resection of the ovaries, in which case only a small segment of normal ovarian tissue remained on each side. In this series, conservative operations were performed on the adnexa in 206 cases; in 300 cases, operation was not required. Also there is an occasional instance in which there is a large degenerating or rapidly growing myoma in an atrophic uterus, in which case it is safer to remove the myoma than to submit the patient to hysterectomy. Such is encountered among elderly patients who are poor surgical risks. The time element in the operation is an important factor. There were three such instances in this

series in which radical removal of both adnexa was performed for associated disease among patients more than 40 years of age, in which cases myomectomy was the primary procedure. Furthermore, there were fourteen instances in which myomectomy was done as a secondary procedure; both adnexa had been removed as the primary operation. Six of these patients were less than 40 years of age and eight were more than 40 years of age. In each case the general condition contra-indicated radical hysterectomy.

MYOMECTOMY DURING PREGNANCY

Myomas associated with pregnancy do not necessarily call for surgical treatment. It is the belief of some

(Bonney, Danforth,⁷ Lynch,⁸ Polak⁹ and Giles) that myomectomy is inadvisable in pregnancy unless the case is very exceptional. These exceptional cases consist of red degeneration or necrobiosis, rapid increase of size of the myomas, and situation of the tumor so as almost certainly to obstruct delivery. Some authors feel that, even in the face of some of these indications, it is better to attempt to carry the patient to term and to treat emergencies as they arise.

We have, in our series, a total of thirty-three cases in which myomectomy was performed in pregnancy.

TABLE 5.—Recurrence of Leiomyomas in 523 Cases After Myomectomy, 1925-1934

* Excludes six postoperative deaths.

Seven of these were ectopic pregnancies, and in four cesarean section was performed coincidentally with myomectomy. By excluding these eleven cases there remain twenty-two cases of intra-uterine pregnancy in which myomectomy was performed. In three instances a very early pregnancy was not known to exist. In thirteen there were serious symptoms of degeneration or necrosis, and in three the tumor and uterus were impacted in the pelvis.

Seven, or 31.8 per cent, of the patients had a miscarriage postoperatively. Fifteen, or 68.2 per cent, did not have a miscarriage. Among these fifteen eleven, or 73.2 per cent, had normal births. There was one case each of cesarean section at term, stillbirth at term, forceps delivery and premature birth, an incidence of 6.7 per cent each (table 4). The figures given by most authors are in accordance with this. Brindeau¹⁰ found that 76 per cent did not have a miscarriage and Gemmell¹¹ stated that 80 per cent had normal children.

RESULTS OF MYOMECTOMY

In evaluating the results of myomectomy it is necessary to consider whether or not the individual has been relieved of the condition for which she sought treatment, the question of recurrence and subsequent surgical procedures that are necessary to effect relief, and the effect of the disease and treatment on subsequent fertility.

These results were computed three or more years after operation. Among the 523 patients there were six deaths, or 1.2 per cent. Of the remaining 517 patients 244, or 47.2 per cent, were cured. There were 111 cases in which recurrences developed. In twenty-six of these cases, recurrence of leiomyomas was proved at subsequent operation here or elsewhere; in eighty-five the diagnosis of recurrent leiomyomas was made after pelvic examination here or elsewhere. The results could not be ascertained in 162, or 31.3 per cent.

11. Gemmell, A. A.: Abdominal Myomectomy, *J. Obst. & Gynaec. Brit. Emp.* 42: 715-748 (Aug.) 1936.

Of these 517 patients 405 were less than 40 years of age and 112 were 40 years of age or older. Of the 405 who were less than 40 years of age, 25 per cent gave evidence of recurrence of tumors, whereas in only 8.9 per cent of those older than 40 years of age was there evidence of recurrence (table 5). The incidence of recurrence in this series, which is more than 20 per cent, is exceptionally high in comparison with the figures given by Gemmell, who summarized the world litera-

TABLE 6.—Treatment Subsequent to Myomectomy (523 Cases), 1925-1934

ture in this connection and found that the incidence of recurrence varied from 0 to 14.28 per cent whereas the probable average is approximately 4 to 8 per cent.

Our incidence of recurrence is amply explained by the fact that in 229 cases, or 43.8 per cent, myomectomy was a secondary procedure and, therefore, complete removal of all tiny leiomyomas which would be necessary to reduce the incidence of recurrence was not performed in every instance.

Not all patients who had evidence of recurrence submitted themselves for subsequent treatment. However, ninety-seven of this group of 111 had some form of subsequent treatment, as shown in table 6. Forty-three were subjected to subsequent hysterectomy, although in only twenty-one was it positively known that myomas were the primary reason for hysterectomy. Nine of the recurring myomas were treated by radium therapy and six by roentgen therapy. In twenty-four cases, subsequent medical treatment of one type or another was administered for menstrual disturbances.

FERTILITY

The incidence of fertility was determined on all patients with the exception of eight in whom the information was not available prior to operation. There were 135 who were unmarried, whereas 388 were married. Of the 388 married women 238, or 61.3 per cent, had been pregnant. Of the 238 women who had been pregnant there were 152 who gave birth to living infants, or 63.9 per cent. Sixty-four, or 26.9 per cent, had experienced only miscarriages, which is presumptive evidence that the leiomyomas were an etiologic factor in the miscarriages. Twenty-two, or 9.2 per cent, were pregnant for the first time when the myomectomy was performed (table 7). There were no pregnancies in 142 cases, an incidence of sterility of 36.6 per cent of the total married group.

Subsequent to myomectomy, sixty-eight of the 409 patients less than 40 years of age at the time of myomectomy became pregnant and bore a total of eighty-four babies, four of which were born by cesarean section and eighty by natural birth.

This figure is further enhanced by the following observations: Six patients were known to be dead at the time of this study, thirty-one were sterilized at operation or within three years after operation; ninety-five were still unmarried; eighty-one of those married

were not heard from with respect to subsequent pregnancy. The postoperative fertility is, therefore, more reasonably calculated on the basis of 196 patients less than 40 years of age, for whom pregnancy could be expected. Of these, sixty-eight became pregnant, an incidence of 34.7 per cent. Finally, if it is assumed that the eighty-one patients whom we could not trace as to pregnancy actually did not become pregnant, the incidence would be reduced to 24.5 per cent, which parallels that given by other authors. Murray quoted the figure 27.3 per cent, Riley¹² 18 per cent, Gemmell 27 per cent and Goulliaud¹³ 25 per cent less than 40 years of age. Bonney, however, stated that 39 per cent of patients within the child-bearing age may be expected to conceive following myomectomy.

SUMMARY AND CONCLUSIONS

Observations in 523 cases in which abdominal myomectomy was performed for uterine myomas, between 1925 and 1934 inclusive, revealed a mortality of 1.14 per cent.

During this period about 3,400 hysterectomies were performed for leiomyomas, giving a ratio of about six hysterectomies to each myomectomy, or about 14 per cent.

There were 294 patients who experienced myomectomy as the primary operation and 229 who were subjected to myomectomy as a secondary procedure.

The operations were performed in each instance as conservative methods to maintain as far as possible the reproductive and menstrual functions. In a few instances, among patients beyond the reproductive period, the adnexa were removed, myomectomy being performed as a secondary procedure; 63.3 per cent of the patients were in the fourth decade of life and the average age of all patients was 36.7 years.

The menstrual periods may be normal among patients who are candidates for myomectomy. In this series the periods were normal in 38 per cent of the cases. Dysmenorrhea was a prominent symptom in 47.4 per cent of the patients who had abnormal menstrual periods.

The situation of the tumor with respect to the uterus is an important factor in performing myomectomy. That is, as far as possible, all myomas should be enu-

TABLE 7.—Fertility in 523 Cases in Which Myomectomy was Performed, 1925-1934

Group	Number	Per Cent
Unmarried.....	135	25.8
Married.....	388	74.2

cleated through the anterior surface of the uterus or through the anterior leaf of the broad ligament so as to minimize the risk of later intestinal obstruction.

Ovarian disease was associated in approximately the same number of cases as that seen in performing hysterectomy for leiomyomas in general. In this series it was 47.4 per cent.

Myomectomy in pregnancy is indicated only in exceptional instances. There were twenty-two cases of intra-uterine pregnancy in which myomectomy was performed. Of these, 31.8 per cent of the patients had a miscarriage

12. Riley, F. R.: Myomectomy in Uterine Fibroids, New Zealand M. J. 27: 68-77 (April) 1928.
13. Goulliaud, M.: Dix-huit cas de grossesse après la myomectomie abdominale, Bull. et mém. Soc. nat. de chir. 5-4: 691-699 (May 9) 1928.

postoperatively. Of those who did not have a miscarriage, 73.2 per cent had normal births; there was only one case in which cesarean section was performed. Myomectomy, therefore, is not to be regarded as too important a factor in subsequent delivery.

The recurrence of leiomyomas in this series was approximately 20 per cent, which is somewhat higher than that currently reported but is accounted for by the fact that 229 of the myomectomies were secondary procedures. It is of importance that 25 per cent of those less than 40 years of age were known to have recurrences, as contrasted with 8.9 per cent more than 40 years of age. Of the group of 111 who had recurrences, only twenty-six required subsequent surgical treatment.

The incidence of fertility was determined for all patients with the exception of eight, or 2.1 per cent, regarding whom the information was not available prior to operation. This incidence was 61.3 per cent, but 26.9 per cent of the fertile patients had experienced only miscarriages.

Subsequent to myomectomy, sixty-eight of the 409 patients who were less than 40 years of age at the time that myomectomy was performed became pregnant and bore a total of eighty-four babies. The postoperative fertility was accurately determined for 196 patients less than 40 years of age among whom pregnancy could reasonably be studied, which gives an incidence of 34.7 per cent postoperative fertility. In the presence of a postoperative incidence of fertility of 34.7 per cent, myomectomy should certainly be regarded as a favorable procedure during the reproductive period, especially when the mortality is not higher than that associated with radical procedures.

ABSTRACT OF DISCUSSION

DR. FRANK W. LYNCH, San Francisco: There is no doubt that myomectomy is not a popular operation and, from the standpoint of modern surgery, that its unpopularity is undeserved. The literature of twenty-five or thirty years ago showed a surgical mortality rate at least twice as much as for hysterectomy. The feeling that the mortality rates are the same lingers still in the minds of many who practice surgery. There are definite reasons why myomectomy was a more hazardous procedure than supravaginal hysterectomy. Uterine muscle that surrounds a growing fibroid hypertrophies just as a pregnant uterus does and involutes later in the same manner, even though in lesser degree. Such tissue does not heal as rapidly as the resting type. The blood vessels nourishing the fibroid are also thin walled, and bleeding is not readily controlled except with some mass ligation. Yet these obstacles to proper wound healing can be readily overcome by proper technic. In the past, the uterine incision was usually closed with through and through sutures, which were often tied too tight, as A. J. Ochsner showed. Nor was there any attempt at proper peritonization. Rough knots of coarse silk or catgut invited dense adhesions, and some degree of intestinal obstruction was not unusual if the case was observed long. With a modern operative technic, all bleeding points are ligated before the uterine incision is closed in layers. Opening the uterine cavity is a matter of little importance if there is proper technic, as the authors have shown. Proper peritonization is vital to a successful operation. There should be no rows of knots of interrupted sutures visible on the uterine incision. A proper closure can be made with only one knot which shows. Aids to peritonization are grafts of omentum or proper utilization of the peritoneal surfaces of the round ligaments pulled back as a Webster cover. With such a technic the patient has little risk. My experience agrees closely with that of the authors, although my series is much smaller. In a series of 1,045 fibroids treated surgically, 42 per cent had supravaginal hysterectomies,

20 per cent panhysterectomies and 18 per cent myomectomies. The surgical mortality rate for the 855 hysterectomies was 0.95 per cent and for the 190 myomectomies it was 0.5 per cent. Forty-one per cent of my patients had tumors larger than 4 cm. Other fibroids have developed requiring subsequent operation in a few. All these women originally had many small tumors. There are no known recurrences in patients whose single tumor was large and deeply embedded in the uterine muscle.

PUBLIC HEALTH ASPECTS OF INDUSTRIAL HYGIENE

R. R. SAYERS, M.D.

AND

J. J. BLOOMFIELD

Senior Surgeon and Sanitary Engineer, Respectively, United States
Public Health Service

WASHINGTON, D. C.

"In recent years," wrote Sir George Newman,¹ "we have learned that public health is not only a matter of the postponing of mortality and the prevention of sickness, but of the positive side of health—the increase of vitality, capacity, and efficiency of the human body. Our aim is not only to oppose diseases but to advance and develop physical fitness and well being. To secure this end, we must have regard to the whole life of man—his heredity and upbringing, his work and rest, his food, his habits, his environment. We must pay attention not only to his actual ailments and diseases, but to the conditions making for a maximum degree of personal health. Thus it comes about that a new relation is found to exist between occupation and health. In a word, the health of the industrial worker forms an integral and inseparable part of the health of the community."

This broad concept of industrial hygiene was enunciated nearly two decades ago and like all fundamental statements is applicable today. Yet, if stock is taken of what has been accomplished in this country during the past twenty years and especially of present practices in this field of public health, it is realized that emphasis has been placed on the control of industrial accidents and occupational diseases. It is not intended to underestimate the importance of accidents and occupational diseases but rather to call attention to the opportunity offered and at the same time to provide assistance to the groups served in the solution of other health problems which are equally, if not more, important. Since industrial health is so closely interwoven with community health, each component part of a broader program is certain to support the other. An analysis of the health problems affecting all wage earners and the present day activities in the field of industrial hygiene will serve to indicate more clearly what may and should be accomplished in the immediate future.

SCOPE OF THE PROBLEM

Industrial hygiene is the science of the preservation of the health of workers. It therefore involves primarily a program for conservation of health and prevention of accidents and occupational disease. Such a program necessarily extends beyond prevention of accidents and occupational diseases; it includes also the broad subject of the health of the worker. It is obvious that some of

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

1. Newman, George: Part of Introduction to Collis, E. L., and Greenwood, Major: *The Health of the Industrial Worker*, Philadelphia, P. Blakiston's Son & Co., 1921.

the problems arise from the nature of the industrial environment itself; namely, the control of poisons, dusts, excessive temperature and humidity, defective lighting, noise, overcrowding and general plant sanitation. Some of them obviously involve such factors as hours of work, fatigue, communicable diseases in the factory, mental health and personal hygiene.

In the past, industrial hygienists have concentrated their efforts in the main on a rather limited portion of the industrial population; namely, the fifteen million workers employed in manufacturing and in mechanical and mineral industries. Although it is true that the greater number of occupational diseases develop among employees in these groups, some of the ten million employed in agriculture and the four million employed in transportation and communication and others should be considered in an industrial hygiene program, for all have health problems which are deserving of attention.

Frequently, workers in establishments hiring large groups in all classes of employment are provided some health services. However, the fact that a large number of workers are employed in small establishments which have no practical means of providing adequate attention to health calls for the cooperation of all interested in the promotion of an effective industrial health program. Of a total of more than eight million persons employed in manufacturing plants, about one half are found working in establishments with less than 250 workers. The obstacles associated with the development of a complete health service for employees in these small units are not unsurmountable if the problem is approached in a cooperative spirit. This means increased activity on the part of all professions and agencies interested in health preservation and that the plans and interests of all need to be correlated. While public health officials may assist most in the administrative and educational phases of the work, the success of their efforts—as in other fields of public health—is dependent on the close cooperation and aid of the group served and the members of organized medicine in the community.

While insufficient data have thus far prevented recognition of some health problems peculiar to wage earners, there is ample evidence to indicate that morbidity and mortality rates are higher for some groups than for all gainfully employed persons or the adult population generally. These excessive rates are especially notable for unskilled workers, for whom the death rate from all causes in certain states was found to be 100 per cent in excess of the death rate for agricultural workers. Studies conducted in specific industries have shown the incidence of such diseases as tuberculosis, pneumonia and degenerative conditions to be higher than the average for the entire industrial population. There is evidence to justify the opinion that deaths from tuberculosis can be reduced 50 per cent by health supervision of workers in occupations predisposing to the disease, by detection of minimal cases and by provision of adequate medical and institutional care in the early stages of the disease. A large amount of information testifies that in a majority of cases the disease is discovered too late in its course for the most effective treatment. It is also known that mortality and disability from pneumonia are excessive among workers exposed to extreme and sudden changes in temperature, inclement weather, toxic gases and dusts.

In view of the means by which the health of the workers can be improved, the problem is complex. First, from the layman's point of view—because the

relationship between cause and effect is more readily discernible—the disability and lost time due to industrial accidents and diseases seem most important. Although great advance has been made in the prevention of industrial accidents during the past twenty years, this form of injury continues to be a major health problem. Incidentally, the industrial hygienist is usually more conscious than others of the part played by ill health as a contributory cause of many of these accidents. According to the last report of the National Safety Council,² there were 19,000 occupational deaths in 1937. Studies indicate also that minimum rates have not been approached, since the records for accidents in the steel companies with the best practices show a rate far lower than that for the industry as a whole.³ Second, it is well known that certain occupations, not necessarily the so-called dangerous trades, are associated with poisoning, disease and high mortality. Third, some workers lack the physical capacity to undertake certain types of work. Fourth, absenteeism due to what may be termed general diseases affecting adults is far too high. While accidents, occupational diseases and high occupational death rates are impressive, there is no doubt that the least dramatic side of the problem—the lost time and incapacity due to illness—is a fact of most importance. Here there is a vast amount of wasted energy and life due in the main to preventable illnesses, some of which may be contributed to by the working environment. Although significant progress has been made in the control of certain communicable diseases, as is evidenced by the declining trend of the death rate in the last forty years, one must not lose sight of the fact that this saving of life has taken place chiefly in childhood and in the years of early adult life. No significant increase occurred during this period in the average years of life remaining to persons of middle and advanced age. The death rates from some important diseases of adult life have been increasing, a phenomenon understandable in the light of the fact that the principal causes of death operating in the advanced years are primarily chronic. Preliminary data from the national health survey, based on surveyed persons of all ages, show that chronic diseases, including permanent impairments, alone account for six of the ten days of incapacity from illness and accidents experienced by the average person per year, and with respect to sickness and accidents, data to be published by the Division of Industrial Hygiene show in the instance of a public utility that on the average 7.5 days were lost annually by men and 10.9 by women.⁴

All these facts have an important bearing on the industrial health problem, since an adult population is involved. The health problems peculiar to workers as a group may be effectively solved by the application of those public health methods which have operated so successfully in the control of specific illnesses affecting other units of the population. In the control of communicable diseases which affect primarily infants and school children, the administrative, educational and professional program has been designed to meet the particular needs. The school authorities, parent-teacher associations and other community groups with the medical profession have cooperated with state and local health agencies in the control of such diseases.

4. Preliminary Reports, the National Health Survey: Bull. 1, Sickness and Medical Care Series, U. S. Public Health Service, Washington, D. C., 1938.

Public health action may in a like manner be brought to bear on problems affecting the health of the worker, since closely associated industrial groups will provide similarly essential and highly important group contacts.

PRESENT TRENDS IN INDUSTRIAL HYGIENE

Government responsibility for safeguarding health rests chiefly with the state and local health departments. The activities of federal agencies engaged primarily in the field of industrial hygiene are established for the purpose of collecting and disseminating information, conducting field and laboratory investigations and protecting the health of federal employees. Prior to 1936 most states had concerned themselves chiefly with matters of safety, sanitation, employment of women and children and compensation of employees following disabling accidents. All but two states have workmen's compensation legislation for accidental injuries, and today twenty-one states provide compensation for one or more occupational diseases. Administratively, the states have placed enforcement of occupational disease legislation in various departments.

During the past two years the United States Public Health Service has, on request, through the Division of Industrial Hygiene, assisted in the development of this field in state and local health departments. Progress has been stimulated in part by funds allotted to the various states for public health activities by the provisions of the Social Security Act. Today there are twenty-three states and four municipal departments of health that have taken steps to provide industrial health services;³ but it must be remembered that these units have been recently established and will not be in a position to render complete or adequate service to industry and labor and the medical profession until they have greatly increased financial support and trained personnel.

At present the industrial hygiene divisions in the states and cities are confining their work chiefly to the evaluation and control of occupational diseases in industry. Occupational diseases have for some time been receiving unusual attention. The reason for the "occupational disease" approach to industrial health problems is logical. First, the relationship between a specific occupational disease and environment is frequently tangible, and the benefits of control practice are evident. Second, the manner in which some diseases have developed in specific industries has been such as to favor dramatization, which in turn has served to make interested groups more conscious of the importance of occupational disease and the need of providing benefits for workers suffering from such illnesses, as in the case of injuries due to industrial accidents.

The thought might bear repetition here that industrial hygiene is essentially adult health maintenance among the gainfully employed and necessarily runs the entire gamut of public health for these persons. Nationwide data to support this view are being collected and analyzed. It is hoped that there will be some basic statistics on the subject of illness and death by occupation in this country as soon as the Public Health Service has had an opportunity to analyze the results of its recent inquiry on more than a half million workers. Limited statistics for the prevalence of occupational diseases are available for a few states. In Wisconsin, where a workmen's compensation law has been in operation longer than in any other state, some recent unpublished data furnished by Dr. William M. Gafaer of this

division bear examination. For the sixteen year period from 1920 to 1935, occupational diseases accounted for 2 per cent of the total cases of compensation. During 1935 this percentage increased to 2.8. During the same sixteen year period 2.8 per cent of the total costs for all injuries was due to occupational diseases, but during 1935 the corresponding percentage increased to 7.1. The compensation cases settled in 1935 represented a loss of over two million working days, and of these days lost 8 per cent were accounted for by occupational diseases. In other words, although the incidence and the costs of occupational diseases are rising, occupational diseases account for but a small percentage of the total compensation cases and costs in the state of Wisconsin. Reports from other states, for example New York, New Jersey and Ohio, show a similar trend. According to the United States Department of Labor, the total direct and indirect costs of industrial injuries in this country are approximately 5 billion dollars annually, and of this amount but a small percentage is accounted for by occupational diseases.

On the other hand, studies made by the American College of Surgeons indicate that illness causes at least fifteen times as much absenteeism as do industrial injuries.⁶ For women lost time from sickness in certain companies has been found to be as much as forty times the number of days lost from work on account of industrial accidents.⁷ Although we have no comparable statistics to show the costs in this country for the so-called general illnesses in the industrial population, individual studies do show that were such information available it would definitely indicate that these costs are far in excess of expenditures due to occupational disease and accidents. Data cited by the Committee on the Costs of Medical Care indicate an expenditure of approximately 10 billion dollars annually due to illness.⁸

It would seem, therefore, that if the general health of a most important and numerous group in the population is to be improved it will be necessary not only to control unhealthful conditions in the working environment but also to give consideration to such factors as proper living conditions, elimination of strain and hurry, nutrition and communicable diseases; in fact, to a general adult health program for workers. A broad industrial health program of this character to progress satisfactorily must be closely interwoven with existing public health activities.

A SUGGESTED PROGRAM

Health officials increasingly emphasize the industrial phase of public health, because any active program among industrial workers will improve the general health in the state. The following method of approach in industrial hygiene, recommended by the Public Health Service, has been undertaken by various states.

The scope and nature of the problems in the state may be established in several ways. If it was possible to obtain statistics for industrial morbidity and mortality as well as for the prevalence of occupational diseases and accidents, there would exist a basis for defining the program. However, such statistics are unavailable except for some accidents, for occupational diseases in a few states and for illness in plants having sick benefit associations. For this reason it has been suggested to

5. There are two divisions of industrial hygiene in state departments of labor.

the various states that they conduct preliminary surveys of representative samples of work places in an effort to obtain information on the potential occupational diseases and health services. The data on health services in particular should prove useful so far as the survey calls for information concerning the keeping of adequate sickness and accident records.

Once the potentialities for occupational diseases have been established by means of this preliminary survey, the industrial hygiene personnel are in a position to select industries for detailed study in an attempt to evaluate each exposure and the means of its control. When studies are completed it should be possible to make definite recommendations for the control of existing or potential health hazards.

By a cooperative program with industrial officials and local physicians, arrangements may be effected for securing reports of occupational diseases and, more important, for investigating the cases so that the cause of the disease may be determined and efforts made to prevent its recurrence. From the preliminary survey, data should be available concerning the extent to which absence due to illness is recorded, and arrangements should be made with establishments to secure uniform reporting of such absences to the state department of health, so that excessive sickness rates by occupation and disease may be determined and means taken for their elimination.

In carrying out these provisions the work should be done cooperatively, and, in addition to furnishing services to physicians, industry and labor, the industrial hygiene unit should be a source of information for other state agencies and the general public. The value of an educational program to acquaint physicians, industrialists, workers and various groups as to the importance of the problem cannot be overemphasized.

At the present time most state industrial hygiene units employ a very small personnel, usually a physician, an engineer, a chemist and a secretary. Even if this number of persons was doubled one could hope for only a limited improvement in the health of all the gainfully employed persons in the state unless all the resources of the health department could be drafted. This is a perfectly legitimate view of the problem, considering the method of approach which may be employed. For example, no one would dispute the fact that many of the diseases of childhood are not directly associated with the school environment; yet, this fact has not deterred health departments and physicians from doing their most effective work in the prevention of childhood diseases through the medium of the school. The same procedure may be attempted in combating adult diseases by approaching the problem through the medium of the factory. For example, the Southern health officer may feel that with the limited number of so-called industrial workers in his state, industrial hygiene activities are not justified. Yet there is no reason why the same health department cannot carry on a program dealing with nutrition, venereal disease, tuberculosis or malaria control through the industrial groups. By so doing it will be practicing effectively the promotion of public health among a large number of people. At present such programs employ the home as a means of contact. It would seem that the approach of bringing public health to the factory should commend itself from the point of view of efficiency alone.

Many health departments have limited the scope of their activities. Most of them are concerned first and

foremost with the control of communicable diseases. This is as it should be, since the primary function of a health department is such control. There is ample justification for widening the scope of health work in a county, district or city to include the prevention of chronic diseases, as the national health survey has shown that chronic disease and permanent impairments alone account for six of the ten days of incapacity from illness and accidents experienced by the average person in a year.

It is desired to stress the fact that in order to carry on any kind of public health work in the factory it is necessary that the personnel know industry and industrial processes, and for this reason the persons expected to guide the work most successfully are those particularly trained in the field of industrial hygiene. As indicated earlier, a large portion of gainfully employed persons who work in small establishments have not as yet been provided a satisfactory industrial health service. The responsibility of the family physician in this phase of the problem must not be overlooked. There must be a closer cooperation between the industrial hygiene personnel in a state health department, the various local public health units and all medical practitioners, in an attempt to bring public health to gainfully employed persons and indirectly to their families.

The situation as regards industrial health constitutes a challenge which the physician ethically and morally, regardless of the particular field in medicine which he has elected to follow, cannot and should not seek to escape. He may assume leadership now with faith in his ability to serve effectively through the promotion of a cooperative and not a competitive broad health program.

ABSTRACT OF DISCUSSION

DR. L. D. BRISTOL, New York: There are a few points which I might emphasize in this brief discussion. First, I like the authors' emphasis on and definition of the scope of industrial health, that it must in the future involve not only occupational disease control but also the promotion of health and the prevention of disease in general among the working population. The health program of the small industry of course needs to be emphasized. Most of the larger companies are doing a fairly satisfactory job now in this field of employee health. As the authors have indicated, the program of the smaller industries might to a certain extent be developed under public leadership, through various divisions of industrial hygiene in state departments of health. They wisely emphasized, I believe, the problem of tuberculosis in industry. Tuberculosis control has been approached through the home, the school and early childhood. If further advance is to be made, the next steps in tuberculosis control must be among employed groups. The whole case finding campaign in industry should be developed as it has been throughout public groups. The U. S. Public Health Service is to be complimented on the work which it has been doing during the last two or three years in helping to develop bureaus of industrial hygiene in various states and making possible the training of personnel with the small funds available.

DR. H. W. GIBBONS, Sacramento, Calif.: We have listened with interest to papers describing the growing efficiency of industrial medicine. Right now, the economics of industrial medicine is important. How are employees of industry who are injured or diseased outside of working hours going to be financed? By government or by private enterprise? As medical director of an insurance company, I am interested in this aspect. Many insurance companies are now issuing group insurance to employees of industrial plants, which covers nonoccupational disease and accident, hospitalization, surgical benefits and life. Sickness and accident insurance for employees disabled in the course of employment is taken care of by state industrial acci-

dent and illness laws and we are agreed that these are developing satisfactorily, but there is an economic stress among this class when the disability is not covered by compensation insurance. Private companies are experimenting with this form of insurance. In theory it works beautifully. One can determine the number of days men have been laid off and the time spent in hospitals and thus establish a satisfactory premium, but, in practice, is the same ratio going to maintain under insurance as it did when the patients had to pay their own way? Will this factor induce the insured to prolong the indemnity period? Will the doctors who treat industrial cases cooperate with insurance carriers in submitting reports and in sending an employee back to work when he is able to work, or will they aid him in claiming all the traffic will bear just because he carries a policy? I should like to suggest that, if the profession and the workers will cooperate, private insurance companies can carry such insurance successfully for a small premium which can easily be borne by the worker and the industry. If, on the other hand, the workers are going to seek more than is their due and physicians are going to help them in that, any plan of insurance will break down. The advance in efficiency of health control in industry coupled with the development of adequate insurance through small contributions is a beautiful plan to contemplate. With the cooperation of all concerned, it will work and there will be no necessity for the government to step in with socialized medicine with the attendant regimentation of our profession.

BLOOD CALCIUM, PHOSPHORUS AND PHOSPHATASE IN URINARY LITHIASIS

PARATHYROID DISEASE AS AN ETIOLOGIC FACTOR

MILES GRIFFIN, M.D.

Fellow in Surgery, the Mayo Foundation
OAKLAND, CALIF.

ARNOLD E. OSTERBERG, PH.D.

AND

WILLIAM F. BRAASCH, M.D.

ROCHESTER, MINN.

Extensive study of the etiology of urinary lithiasis by numerous workers has failed to produce a factor which can be considered as primary in all cases of stone formation in the urinary tract. However, much knowledge has been gained regarding predisposing and contributing factors. The relationship of infection and stasis to the occurrence of urinary lithiasis has been mentioned repeatedly,¹ and the role of urinary colloids and crystalloids in the formation of stones has been referred to.² The urinary excretion of such substances as cystine³ and uric acid⁴ are known to predispose to calculi of similar composition, and vitamin deficiencies, diseases of nutrition⁵ and other metabolic disorders⁶ and

organic diseases⁷ have been studied and designated as factors of an importance which varies widely with individual authors.

Since so many urinary stones are compounded calcium and phosphatic salts, studies of calcium and phosphorus metabolism have been followed with much interest by urologists. Comparatively recent and thorough investigative work on hyperparathyroidism has revealed that 27 per cent of a series of eighty-three patients with this disease had renal calculi.⁸ Some investigators⁹ have stated that parathyroid disease is the apparent etiologic factor in at least 10 per cent of the cases in which stones form in the urinary tract. Later, from 4 to 5 per cent was given by the same authors⁹ as a more correct figure. It occurred to us that, if from 4 to 5 per cent was a figure representative of the incidence of parathyroid disease in cases of urinary lithiasis for the country at large, we were not recognizing hyperparathyroidism as frequently as it occurs in cases of urinary lithiasis. The purpose of this study was, therefore, to investigate the incidence of parathyroidism in cases of urinary lithiasis.

In this study, 1,206 consecutive cases of urinary lithiasis were examined for clinical evidence of hyperparathyroidism. Of this number, in 229 cases particular attention was paid to laboratory studies, including determinations of blood calcium, phosphorus and phosphatase. The range of from 9 to 11 mg. of calcium, from 3 to 4 mg. of phosphorus, and 5 units or less of phosphatase per hundred cubic centimeters of blood was used as a standard for normal evaluation. Admittedly these are narrow limits, and slight variations above or below them have not infrequently been found in other cases without urinary lithiasis or any demonstrable organic disease. Nevertheless, we felt it advisable to adhere to this narrow standard for normal values in order to insure detecting any early change which might be present in the blood of patients with urinary lithiasis. Calcium was determined by the procedure of Clark and Collip,¹⁰ calcium oxalate being allowed to precipitate over night. Values for phosphatase were expressed in so-called Bodansky units and were determined by the technic described by Bodansky.¹¹ Phosphorus was determined by the technic of Kuttner and Lichtenstein.¹² We feel that these methods give results that are exact and are easily reproducible.

In these 229 cases of urinary lithiasis in which particular attention was paid to laboratory studies there were 111 cases in which the results with respect to the calcium, phosphorus and phosphatase content of the blood were higher or lower than normal in one or more determinations. In such cases the determinations were usually checked one or more times. Of these 111 cases, there were seventy-one in which the value for blood phosphorus was low and thirteen in which it was

high in combination with normal values for calcium and phosphatase. Converting these figures into percentages, 31 per cent of the patients (seventy-one of 229) had low values for inorganic phosphorus and 5.7 per cent (thirteen of 229) had high values for phosphorus. For 31 per cent of the patients to have a lowered value for blood phosphorus is surprising, although the significance of this is lessened by the fact that less than half of the seventy-one patients who had a low value for blood phosphorus had a reading of less than 2.6 mg. per hundred cubic centimeters. As one might expect renal insufficiency to be present more frequently in cases of lithiasis, one might also expect a greater percentage of hyperphosphatemia as compared to hypophosphatemia because of the kidneys' inability to excrete phosphorus.

A high value for blood phosphatase was combined with a low value for blood phosphorus and with a normal value for calcium in five cases, although the value for phosphatase was significantly elevated in only three of these cases. Three of the five patients had a value for phosphorus of 2.8 mg., and two of 2.4 mg. per hundred cubic centimeters of blood. The value for blood phosphatase was high in combination with a normal value for blood phosphorus and calcium in ten cases, but this elevation was so slight as to be considered normal except in three cases. With exception of cases of hyperparathyroid disease, we found the high value for blood phosphatase related not so much to urinary lithiasis as to coexistent disease elsewhere in the body; namely, hepatic disease, osteitis deformans, arthritis and traumatic and metastatic bone conditions. The combination of low values for blood calcium, phosphorus and phosphatase was found in only one case.

The value for blood calcium was high in three cases and low in three cases, in combination with normal values for phosphorus and phosphatase. An elevated level of blood calcium was combined with a low value for phosphorus in three cases and was combined with high values for phosphatase and a low value for phosphorus in two. In only four of the eight cases in which the value for blood calcium was elevated was the value for blood calcium more than 12 mg. per hundred cubic centimeters. It is interesting to note that the highest value for blood calcium was 14.7 mg. per hundred cubic centimeters; it was encountered in a case of hyperparathyroidism.

In only the two cases in which the value was high for blood calcium and phosphatase and low for phosphorus was the diagnosis of hyperparathyroidism made. The chief complaint of one of these two patients was recurrent renal calculi, and a parathyroid tumor was found on surgical exploration. The values for calcium, phosphorus and phosphatase in the blood were 14.7 mg., 2.6 mg. and 10.2 units per hundred cubic centimeters of blood, respectively. Bilateral renal lithiasis was present in the other case and a clinical diagnosis of hyperparathyroidism was made; however, a parathyroid tumor was not found on exploration. The values for calcium, phosphorus and phosphatase in this case were 12.1 mg., 1.7 mg. and 9.8 units per hundred cubic centimeters of blood, respectively.

Albright⁶ and others reported that 27 per cent of a series of twenty-three patients with hyperparathyroidism were proved at operation to have renal calculi. The two patients with hyperparathyroidism in our series

had calculi, but hyperparathyroidism did not occur often enough to be considered a factor in the etiology of urinary lithiasis. Lloyd¹³ cited a series of 10,000 consecutive necropsies in which only five parathyroid tumors were found.

Our study of the chemical constituents of the blood of patients with urinary lithiasis has therefore failed to throw much light on the uncovering of the definite factor in the etiology of stone formation. Albright and Bloomberg¹⁴ have aptly said, "The practical question in any one case where there is a tendency to form renal stones is not what is the cause of stone formation but what in that individual predisposes him to stone formation." Undoubtedly some people have a higher protective factor than others. The cause of stone formation is not just the presence of excess amounts of substances which predispose to stones of like composition. Aub and others¹⁵ found the urinary excretion of calcium and phosphorus increased to 231 per cent above normal in hyperthyroidism. Yet urinary lithiasis is relatively not a common complication of hyperthyroidism. Farquharson and his associates¹⁶ reported studies in which making the diet acid or adding ammonium chloride to the diet increased the urinary excretion of calcium and phosphorus up to 400 per cent. Yet in our very recent experience the solution of recently formed renal stones has occurred in two cases on administration of acidifying drugs. Clinically, the elusive factor in the etiology of stone seems to be as closely related to phosphatase activity as to hyperphosphaturia and hypercalcinuria. It is not so rare to observe orthopedic cases in which stones are being formed while the patient is in the hospital. Such references are frequently encountered in the literature.¹⁷

Some of the results of determinations of blood calcium and phosphorus in cases of urinary lithiasis reported in the literature vary greatly from the values we obtained. One author¹⁸ reported that 78 per cent of thirty-seven patients with urinary lithiasis had a value for blood calcium above normal, the average value for blood calcium being reported as 12.17 mg. per hundred cubic centimeters. Kerley and Lorenze,¹⁹ however, reported a series of 294 cases (all children) in which determinations of blood calcium and phosphorus were made, and found only seven children who had significant symptoms which were related to these observations.

CONCLUSIONS

In cases of urinary lithiasis the values for blood calcium, phosphorus and phosphatase exhibit no common change which can be termed characteristic of the group. Minor variations in the value for blood phosphorus, particularly a lowered value, are not unusual but the concentration of blood calcium is very constant.

Patients with a high value for blood calcium or phosphatase who have urinary calculi should undergo a thorough investigation for some other coexistent pathologic condition.

In our study, hyperparathyroidism was found to be an etiologic factor in less than 0.2 per cent of the 1,206 cases of urinary lithiasis.

A TREATMENT FOR THE SUPERFICIAL MYCOTIC INFECTIONS OF THE GLABROUS SKIN

DOUGLAS T. PREHN, M.D.

Lieutenant (Medical Corps), U. S. Navy Dispensary, Navy Yard
NEW YORK

Skin diseases produced by fungi make up most likely the largest single group of dermatologic diseases, and for that matter make up perhaps the most common diseases of man. This is especially true where human contact is intimately frequent, as in schools, prisons, institutions, colleges, ships, clubs, dormitories, bathing beaches or pools and other places where people congregate or live close together. It is also easily conceived that infection is extensive in homes where incidence surveys have not been made or reported. Osborne and Hitchcock¹ estimated that 90 per cent of male college students indulging in athletics, from 25 to 50 per cent of high school students and 50 per cent of the general adult population have ringworm of the feet. Legge, Bonar and Templeton² found that 53.3 per cent of the men and 15.3 per cent of the women of the 3,100 freshman were infected, and at the terminal period of the spring semester that 78.6 per cent of the men and 17.3 per cent of the women had ringworm of the feet.

Other estimates of the incidence of glabrous skin mycotic disorders are similar to those cited.³ Eleven ships of the U. S. Navy, six in the Orient, four on the West Coast and one on the East Coast, were surveyed, and of the 1,500 men examined 92 per cent were found affected in the early or more severe stages of ringworm disease of the glabrous skin. In 88 per cent of the cases the mycotic infection was found most prevalent between the toes or on the feet, 15 per cent on the inner thigh-scrotal-anal region, 1.8 per cent on the hands, 2.3 per cent in the axillae and 2.3 per cent in the external auditory canal of the ears.

The statement is made⁴ that no general systemic condition such as acidosis is responsible, since healthy as well as sick persons are subject to the infection. Furthermore, the infection is not always a mild disease: Of 161 consecutive patients fourteen were

totally disabled and thirty-two were partially disabled, and in some instances the disability lasted as long as three months. One might also add here that secondary infection is not infrequent and may subsequently develop into severe conditions, becoming a focus for septic complications or even a septicemia. The hospitals could reveal the large number of such complications.

The clinical appearance is the simplest and most reliable practical diagnosis. There are many classifications presented⁵ of the different types of glabrous skin mycotic infections and many different types of fungi responsible for the lesions of the skin. These will not be discussed here. When in the history of a case the toxic contacts, the general systemic diseases such as syphilis and the susceptible sensitizations of the patient have been eliminated and a history of exposure to ringworm disease in suspected places or to infected persons has been established, the localized areas of the skin affected with the clinical appearance of the lesion will usually picture the condition. The whitened, macerated, sodden mass of epithelium between the toes most frequently found between the fourth and fifth toes and in the external auditory canal of the ears, the fissured, scaling, eczematous areas on the hands or feet, the vesicular and pompholyx or bullous lesions on the soles or on the lateral surfaces of the fingers and feet, the flattened pigment-like or moist copper-red areas with a spreading margin found on the inner thigh-scrotal-perineal-anal areas commonly known as *tinea cruris*, the axilla erythrasma resembling the *tinea cruris* lesion often involving the folds of the skin beneath the breasts or the folds of the pendulous abdomen, the less frequently encountered pityriasis versicolor, the circinate *tinea* infections and the chronic eczematoid ringworm, often hyperkeratotic, involving the soles of the feet and occasionally extending to the legs, or when on the hands to the forearms with or without scattered vesicles and pustules are all well known manifestations of the mycotic infections of the glabrous skin.

The differential diagnosis may be difficult in some cases, and the aid of microscopic examinations (less than 50 per cent positive), patch and intradermal tests and cultural and biochemical investigations may be of assistance; however, these methods are still too indefinite for practical routine use. Much confusion exists concerning the apparent differences between the clinical pictures of vesicular eczematous and scaling fungous ids and those from contact allergens or irritants and other causes, but, as Wise and Sulzberger⁶ point out, they are convinced that in most cases no definite distinction can be made on clinical and morphologic grounds and, as far as the actual topical therapy of the presenting manifestations is concerned, there need be little if any difference in the form of treatment selected to combat eczematous eruptions due to other causes. This idea of diagnosis and treatment of fungous infections on the glabrous skin, in the main, holds true with other eczematous and eczematoid processes that resemble or are contributory factors of the same dermatologic picture.

The prodigious methods and drugs used in the prevention and treatment of mycotic disorders of the glabrous skin serve only to confuse the physician as well as the patient. The experts practically all state that roentgen therapy helps materially in shortening the course of the infection, but a long series of roentgen treatments serves no good purpose, does not permanently cure and should be avoided. Carpenter^{5c} discusses eleven popular medicaments and then states that such an extensive armamentarium tends to produce much confusion, and the selection of what is best becomes a wearisome procedure of trial and error. Wise and Sulzberger^{5a} offered a limited number of drugs, but more than fifty were outlined for selection. The more commonly known medicaments (the favored Whitfield's, Deck's ointments),⁶ the volatile oils,⁷ the tinctures (iodine),⁸ the paints (as Castellani's),⁹ the solutions (potassium permanganate or sodium thiosulfate)¹⁰ and many other forms of treatment¹¹ were tried in many hundreds of cases in my experience, without any appreciable success or confidence in their routine use.

To cite one example of unsuccessful venture with one of the aforementioned treatments, an attempt was made to use the preventive sodium thiosulfate solution as recommended by Osborne.¹² The men on four ships of the Fifteenth Destroyer Division in the Far East totaling 520 men were carefully examined for clinical evidence of mycotic disorders of the glabrous skin. Ninety-three per cent were affected in some stage of so-called athletes' foot. The 6 per cent found with more extensive lesions were treated locally daily in the sick bay with different remedies, and the others were instructed to use daily the available foot baths of 10 per cent sodium thiosulfate placed in the wash rooms. It was advised that socks be boiled before they were worn. The shoes were washed inside and dried during the night for wear in the morning. It was believed that the frequent scrubbing, done more than once daily, and the subsequent splashing of the foot bath solution on the deck would aid in exterminating the source of infection or reinfection. Two monthly inspections of the feet, including the short-arm inspection, followed by lectures on the care of the feet were held. After five months of this regimen 25 per cent of the 520 men were found still to be infected. The last three inspections found little improvement in reducing the incidence of the infection. Several factors may have contributed to the failure in reducing the incidence below 25 per cent.¹³ On the question of reinfection from the shoes, gasoline was tried for a month during which the men were instructed to

wash out old shoes on the inside, allowing them to dry during the night at least twice a week. As this did not seem to make much difference in the reduction of the incidence, this procedure was abandoned. There was also a tendency of the men to avoid the foot baths owing to its dirty appearance after many had walked through it, and probably the uncomfortable feeling of a cold foot soaking following a bath added to this lack of complete cooperation; however, at least in the afternoon the men's clean-up was usually supervised by a member of the medical department. The idea seemed good and the method was pushed as there was a known reduction of the incidence; yet the ultimate complete success was not accomplished. Sodium thiosulfate wet dressings on more advanced active lesions was found entirely unsatisfactory and was abandoned in favor of other methods. This failure was later explained.¹⁴

A search for a satisfactory routine remedy over a period of seven years revealed the following:

The ointments were abandoned because they have the faculty of soiling the user's wearing apparel and other places with which they come in contact, they render an undesirable cosmetic appearance, being especially unsightly on the exposed surfaces, they are defiling and blotchy in application, and it is also possible that they assist in the spread of the infection or have a tendency in rendering the skin practically impermeable to the contained ingredients, thereby causing uncertain therapeutic action. Wise and Sulzberger^{5a} state that ointments have a tendency to dam up secretion, plug follicular orifices and produce follicular infection and irritation. All the undesirable characteristics are more profound as and when the disease is found, most prevalent in the summer months or in tropical climates. Here the increased irritable heat of the body with the resulting increased perspiration spreads the melting salve on the surface, increasing its undesirable characteristics.

Liquid forms of treatment usually contain evaporating volatile substances, such as alcohol, which soon change the characteristics of the remedy, especially if the container is left uncovered, as frequently occurs with tincture of iodine. Owing to the natural oiliness of the healthy skin and the surface tension afforded by the skin secretions, an infected part held in solution for an extended period, which is usually necessary in skin lotion therapy, may allow the lotion to break down the natural barriers, causing a further extension of the infection into the adjoining uninfected skin. Also solutions, most of them made up with a dehydrating agent, may rapidly dry the skin or mummify it so that deep-seated extension of the applied remedy is difficult, thereby causing assistance to the infection and its further undermining extension. Dye paints, such as Castellani's paint, are most unsightly, stain the clothing as well, and have very little to offer in overcoming the infection as compared to other remedies. Applied wet dressings or compresses, unless repeatedly kept moist, soon dry out, adding irritation as a foreign body to the already irritated affected part. Any moist dressing is uncomfortable and avoided by the patient when not confined to bed. Soaks such as foot baths have the undesirable properties already mentioned and in addition are time consuming, which is always annoying to the patient. Relating to the proprietary remedies, most authors agree in their condemnation.¹⁵

It would seem, therefore, that the simple method of application of powder rubbed into the affected part offered the best means of local therapy on the mycotic infected glabrous skin and, with the expectation of the patient's cooperation, various prescriptions of powder remedies were tried. Some were more successful than others. After process of elimination the compounds of salicylic acid, boric acid, camphor, menthol and starch were found most satisfactory. A pharmaceutical analysis of the properties gave the clue for their successful use. Briefly, the formula has a keratolytic action which allows the ingredients to attack directly the infection beneath the surface of the dead skin. However, even as salicylic acid is an exfoliant and assists in stimulating resistance, it is usually quite irritating in higher percentages of from 1 to 3 when applied directly or in other known combinations, especially to an inflamed skin. This formula revealed a synergic action with the other ingredients, allowing even higher percentages than the usually sufficient 5, without interfering with the soothing qualities of the formula's analgesic property, most necessary to relieve the pruritus often encountered in this type of infection. The antiseptic and bactericidal or fungicidal property is well supported by the contained ingredients, allowing penetration directly to the lesion, fulfilling its mission and possibly sufficiently overcoming the allergens in the dead as well as in the surrounding skin. The gentle stimulating property brings about a mild hyperemia augmenting the process of resistance and repair. The demulcent property soothes and allays the irritation of inflamed and abraded skin, which is assisted by the absorption of irritating secretions, thereby preventing excoriation. Extreme gentleness in the action of this compound can be accomplished by diluting the ingredients with more starch.

The method of application of the compound is important. The powder should be thoroughly rubbed into the skin at least daily or more frequently, depending on the severity of the infection. When pustules or bullae form, the roof should be cut from the raised lesion and the powder thoroughly rubbed into the raw diseased surface or exposed area. Any loose skin should be torn or cut away, as likewise all scales should be removed and the powder triturated into the diseased and surrounding skin. Jamieson and McCrea^{13d} emphasize the necessity of applying remedies to normal skin adjacent to the lesion since the fungi were found in normal skin from 1 to 2 inches outside the active lesion. Also, the powder should be rubbed on the skin for several weeks after the lesions have apparently cleared up in order to prevent its reappearance as the result of the ever potential reinfection. In this way it serves as a prophylactic powder. As a prophylactic powder, especially necessary when there is continuous known exposure, it seems sufficient to use it weekly and in many cases it has prevented recurrence or new infection when used monthly. No harmful effects have been noted on clothing, shoes or other material with which it comes in contact; instead, it probably assists in exterminating the source of infection or reinfection.

The most suitable formula found for routine use in the prevention and treatment of the superficial mycotic disorders of the glabrous skin is salicylic acid 5 Gm., menthol 2 Gm., camphor 8 Gm., boric acid 50 Gm. and starch 35 Gm.

A clinical trial with this powder formula was carried out on affected men aboard five ships, the Fifth Destroyer Division and the U. S. S. *Mahan*, where 91 per cent of the men, or 576, were found infected on the initial clinical inspection or examination. Eighty-seven per cent had the infection on the feet, of which 20 per cent had the pompholyx type of infection and 5 per cent the eczematoid type. Twelve per cent of the 576 men had the disorder in the thigh-scrotal-anal region—*tinea cruris*—of which only six complained of itching symptoms while the others did not know they had the infection. Sixteen of these sixty-nine men also had an infection of the feet, two men had infections of the external auditory canal and one had an infection on the hands. Three per cent of the 576 men affected were found with axilla erythrasma, of which five cases were unilateral, seven had involvement of the foot and two had *tinea cruris*. Twelve men, or 2 per cent of the 576 men, had infections of the hands, of which five men, including myself, had a severe pompholyx with an eczematoid extension involving the hands and wrists and in two cases the forearms. Ten men were found with an infection of the external auditory canal—the macerated, sodden mass combined with swelling and inflammation. It may be well to mention here that the external auditory canals were first cleaned out by irrigation or by an applicator, and, when the swelling occluded the canal, drops of the same formula made into a liquid with alcohol were added or wet plugs of the liquid were inserted until the swelling subsided sufficiently to allow application of powder. The other men were given about 2 ounces (60 Gm.) of the powder in a paper and told to rub it in three times a day, saving the spilled overflow of the powder on the paper to be used over again.

On the second inspection, from ten days to two weeks later, as the men were available, the incidence of infection was reduced to 30 per cent. In contrast to the sodium thiosulfate experiment, the men all seemed eager to cooperate and apparently all were using the powder as advised. In fact, some of the men who were not affected asked for the powder and used it as a prophylactic.

On the third inspection, which was about a month following the initial inspection, the incidence was reduced to less than 5 per cent. On the fourth inspection, completed two months after the initial inspection, no cases were discovered.

Of the five men with severe infections of the hand, three, including myself, were free from all inflammation and mycotic evidence in two weeks, except for a slight cutaneous scaling, no doubt due to the keratolytic action of the salicylic acid. The remaining two cases were cleared up a week later.

It was not possible to observe the men personally for more than two months after the completion of the treatment, and on one ship, the *Mahan*, no later check-up inspection was made. However, it is believed as a result of subsequent observations on persons who were cured of this condition that the prophylaxis remained secure, especially if the men were instructed to continue the powder periodically and on the first appearance of any evidence of infection to use the powder oftener.

CONCLUSIONS

From the clinical trial presented it seems that the powder formula has a specific application in the preven-

tion and in the routine treatment of the superficial mycotic disorders of the glabrous skin including mycotic diseases of the axillas and the perineal regions.

SUMMARY

1. There is evidently a high incidence of mycotic infection of the glabrous skin—found to be 92 per cent of 1,500 men clinically examined aboard six ships.

2. Ten per cent sodium thiosulfate foot baths were used as a prophylactic for ringworm infection of the feet on four ships having 520 men, resulting in reducing the incidence from 93 per cent to 25 per cent in five months of trial.

3. The use of sodium thiosulfate wet dressings on more advanced active lesions of ringworm infection was found unsatisfactory.

4. A formula suggested for a powder used as a routine by 576 men found infected with mycotic lesions of the skin aboard five ships reduced the incidence of infection from 91 per cent to 30 per cent in about two weeks, to less than 5 per cent in about a month, and to no infection in about two months.

RABIES

REPORT OF TWELVE CASES, WITH A DISCUSSION OF PROPHYLAXIS

MAURICE L. BLATT, M.D.

SAMUEL J. HOFFMAN, M.D.

AND

MAURICE SCHNEIDER, M.D.

CHICAGO

Between January 1929 and January 1937 twelve patients with rabies were admitted to the Cook County Hospital. All died. The diagnosis in each case was confirmed by autopsy. Rabies continues to take its deadly toll of human life, year after year, notwithstanding Pasteur's development of a successful prophylactic treatment more than a half century ago.

The series here reported comprises seven children and five adults; eleven were males; one was a Negro. The age and the racial incidence are in accord with those generally accepted, and the racial incidence evidences a certain amount of immunity in the Negro. The preponderance of males is explained by their more frequent contact with dogs.

The incubation period for our patients varied from two weeks to two months. The closer the site of the bite to the central nervous system the shorter was the incubation period. This fact was exemplified in the case of J. O., who died three weeks after receiving a bite on the face, as compared with that of W. W., whose death occurred two months after he was bitten on the foot and thigh. There was a history of preceding malaise of from two to seven days. The seven day prodrome occurred in a 17 year old white boy. He had a dog bite of the lower lip. No local treatment had been given, but he had received twenty-one daily injections of antirabic vaccine beginning one week after the injury. Immunization failed in one other child in this series. He was a white boy of 5, bitten on the face. He received no local treatment, and his inoculations were not begun until one week after the dog bite. Twenty-one injec-

tions were given in fourteen days. His prodromal symptoms began one day before the completion of the series. Three days later he died. Immunization failed in the only woman in the series. She received fourteen injections, begun one month after the bite. Active symptoms began one month after the injections had

Fig. 1.—The cry accompanying the pharyngeal spasm of rabies. The illustrations are reproductions from a 16 mm. motion picture film made by us in 1932. None are of patients reported in this series.

been completed—two months after injury. Her bite occurred on a finger, and the history states that the wound was cauterized. It does not state when or with what agent. Death resulted in every case in less than thirty-six hours after admission to the hospital.

In our series, early symptoms, when taken in conjunction with the history of a dog bite, were sufficient for diagnosis. In every instance the earliest symptom was associated with the central nervous system. Each patient gave a history of a marked change in disposition

Fig. 2.—The refusal to accept water.

at the onset of the disease. The early stage varied in length from one to seven days. No patient was brought to the hospital in this stage.

On entrance to the hospital, patients not in the terminal stage were mentally clear and soon became talkative, very agitated and physically hyperactive. Accompanying the periods of agitation there were frothing at

the mouth, inability to swallow and vomiting—in most instances of a bloody fluid. After such an episode the patient would be exhausted and lie quietly in bed. Convulsive seizures could be brought about by the slightest mental or physical irritation. These symptoms continued until the patient became completely narcotized, exhausted or comatose.

Pharyngeal spasms occurred and were of such severity as to cause the patient to clutch his throat and shriek in agony. Drooling of bloody saliva continued during the periods of quiescence as well as with the convulsive seizures.

Violent generalized clonic convulsions without loss of consciousness occurred in nine cases. There is no known

lowing was impossible, and the effort produced pain and convulsions. Even the sight of a drinking cup apparently started pharyngeal peristalsis and precipitated a spasm of the pharynx or generalized convulsions.

Temperatures varied from 103 F. (rectal) on admission to 108 F. at death. The pulse was rapid and out of proportion to the fever and increased in frequency with each convulsion.

The laboratory examinations gave indefinite results. No conclusion could be drawn from study of the blood, since in three cases it showed leukocytosis and in one, that of a child, leukopenia. Two of the patients had albuminuria and glycosuria, while a third had only albuminuria. Spinal punctures were done in five of the

Observations in Twelve Cases of Rabies

Name, Age, Sex, Color	Incubation	Days Ill Prior to Admission	Dates of Admission and Death	Site of Bite	Prophylaxis		Symptoms	Laboratory Examinations
					Local	General		
1. E. R. 21, ♂ white	Not definite	Three	2/12/29-2/12/29	No history	0	0	Pain in left arm; maniacal; choking spells on drinking; arm and face swollen; expectorated freely; clear mentally; no convulsions	W.B.C. 26,000; R.B.C. 4,500,000, neutrophils 85, lymphocytes 15, albumin 3+, sugar 4+; spinal fluid normal
2. L. S. 51, ♂ white	1 month; 6/8/29 2 months	Two	7/29/29-7/30/29	Right hip	Unknown	0	Semicoma; frothed at mouth; angry spells; difficulty in swallowing; bloody vomitus; convulsions	Spinal fluid normal, albumin in urine 4+, sugar

B. 44, ♀ white	7/20/29	Four	9/17/29-9/19/28	Finger of right hand	Cauterization, date unknown	14 injections, begun 1 month after bite	Weakness of right hand at 1 week; inability to swallow water; restless; talkative; no convulsions	Spinal fluid 2+, Ross-Jones reaction 2, lymphocytes 125, W.B.C. 16,200, albumin 4+, many casts and white blood cells
4. L. S. 6, ♂ white	No history	Three	5/27/32-5/27/32	No history	0	0	Fever; dyspnea; nausea and vomiting; unable to drink water; mild convulsions	0
5. N. J. 6, ♂ Negro	1 month; no history	Two	10/15/34-10/15/34	Over forehead	0	0	Headache, pain over right eye; periods of agitation; would not drink; frothing at mouth; convulsions	Spinal fluid normal, W.B.C. 23,100, neutrophils 56, lymphocytes 14
6. L. M. 17, ♂ white	1 month	Seven	6/14/35-6/15/35	Left lower lip	0	21 injections, begun 1 week after bite	Difficulty in swallowing; pain in jaw and face; convulsions	0
7. W. W. 7, ♂ white	2 months; 10/7/35	Three	12/8/35-12/9/35	Foot and thigh	0	0	Nervous; twitching; difficulty in swallowing; vomiting of white foamy material; convulsions	W.B.C. 20,000, neutrophils 85, lymphocytes 15, albumin 3+, sugar 4+; spinal fluid normal
8. C. R. 9, ♂ white	4-5 weeks	Two	8/16/36-8/17/36	Right wrist	0	0	Pain in back; nervous; irritable; difficulty in swallowing; vomiting of white foamy material; convulsions	0
9. W. R. 6, ♂ white	6 weeks	Two	9/4/36-9/5/36	Left cheek	0	0	Frightened; difficulty in swallowing; nervous; vomiting of mucus	0
10. J. S. 25, ♂ white	7 weeks; 7/15/36	Two	9/3/36-9/3/36	Left hand	0	0	Abdominal pain; vomiting; jerky movements of arms and legs; wildly disoriented; pupils did not react to light	Spinal fluid normal
11. J. M. 12, ♂ white	Two weeks	Two	10/4/36; died in one hour	0	0	0	Convulsions; vomiting; jerky movements of arms and legs; wild, disoriented; pupils did not react to light	0
12. J. O. 5, ♂ white	3 weeks; Bitten 6/7/36	Two	6/29/36; died in two hours	Face	0	21 injections, begun 1 week after bite	Fever; irritable and "crabby"; convulsions; frothing at mouth	0

clinical disease in which they are as severe. The movements simulated those produced by the rapid make and break of a powerful induced galvanic current. The patients tossed about without control and, unhappily, without loss of consciousness. One little boy, whom we observed closely, cried piteously to be held to prevent the violent movements. Mentally he was more than usually alert during the seizures. Two of the adults and one child had no convulsions at any time.

An expression of anxiety, widening of the palpebral fissures, with exposure of the scleras, and the wide-open mouth accompanying the cry of terror made up a fairly typical facies in the children. There was little or no blinking of the eyelids after the disease became evident. With each attack of pharyngeal spasm the mouth was opened wide and there was a shriek of terror. Swal-

lowing was impossible, and the effort produced pain and convulsions. Even the sight of a drinking cup apparently started pharyngeal peristalsis and precipitated a spasm of the pharynx or generalized convulsions.

Treatment was entirely symptomatic. Its object was to induce rest, prevent suffering and control convulsions. Large doses of sedatives were needed. In adequate doses chloral, bromides, avertin with amylene hydrate and morphine were equally effective. A dark, quiet room without drafts or other disturbances was conducive to control of the convulsions. Attempts to give food or liquid are contraindicated.

We are presenting, in the accompanying table, the clinical histories of these patients for the purpose of encouraging active interest and militant effort toward the eradication of this universally fatal disease. Eradication must be brought about through the education of the public to the dangers of uncontrolled dogs, to the possible result of an animal bite and to the necessity for the immediate medical treatment of such a bite.

Fig. 3.—This is not tear of water. It is the patient's recognition of the inability to swallow.

Since in over 90 per cent of a large series of reported cases (and in all of ours) the disease occurred as a result of a dog bite, first attention should be directed to the elimination of the disease in this animal. To accomplish this the following measures are necessary: (1) the institution of an effective national and interstate quarantine period of observation for dogs not constantly caged or on leash, (2) the impounding or destruction of all stray dogs, (3) the rigid enforcement of statutes relating to licensing and to the impounding as strays of dogs not licensed, (4) the requiring of anti-rabic inoculation of all dogs as a requisite to the issuance of a license and repetition of inoculation at six month intervals¹ and (5) the muzzling of all but working dogs when not on leash or on the owner's premises.

The second phase of the problem demands the prompt reporting of all bites to public health authorities so that the dog which has inflicted a bite may be placed under veterinary observation for two weeks.² As a rabid animal lives but five or six days, a dog which lives beyond that period and does

Fig. 4.—The palpebral orifice between convulsions. This wide-eyed stare is constant and characteristic.

not acquire the disease in the two weeks of observation may be considered nonrabid and returned to its rightful owner. Strays should be publicly impounded and destroyed. If avoidable, a dog should not be killed during capture. If it is killed or dies while under observation, the brain should be examined for Negri bodies.

The bitten person must report immediately to a physician for treatment. The treatment of animal bites has been standardized. Deviation from the standard is not in accordance with medical experience. Every animal bite in which the skin is broken should be cauterized immediately with fuming nitric acid, a glass rod or capillary pipet being used. The acid should be carefully used and not neutralized. Such cauterization not only insures against the pyogenic infection common after bites but if done thoroughly within forty-eight hours is an important factor in the prevention of rabies.³

Antirabic vaccine should be administered (1) to any person bitten by or contaminated in any way by the saliva of an animal known to be rabid and (2) to any one bitten by an uncaptured stray animal.

When the bite is on the head or the neck, administration of the vaccine should be begun immediately but may be discontinued if the animal is proved nonrabid after impounding and observation. A negative report for Negri bodies on an animal killed before sufficient time has elapsed for such bodies to form is not an indication to discontinue treatment.

When the bite is by a sick dog or a dog which becomes sick while under observation, injections should be continued until rabies is definitely ruled out. If the report is positive, the series of injections should be completed.

The Semple modification of the Pasteur treatment is commercially available and should be given twice daily for from twenty-one to twenty-eight doses for a bite about the head or neck. For a mild bite in a region of the body distant from the brain, fourteen daily doses are considered adequate.

In the series of cases here reported not one patient was treated in accordance with the rules mentioned. In some instances cauterization was done late or not at all, and in others the administration of vaccine was begun late or not at all. The result was death.

The effectiveness of antirabic vaccine is best estimated from the statistics reported by McKendrick.⁴ He reports that 162 persons (0.23 per cent) died of rabies in a series of 69,541 who had been given prophylactic vaccine. There were nineteen instances of post-vaccinal paralysis, a percentage of 0.027, in his series. No analysis of cauterization in his series is available.

Statistics on dog bites in the United States are not available. However, Illinois may be considered as a "sample" of the occurrence of bites in thickly populated states. In 1936 in this state 18,466 persons were reported to the department of public health as having been bitten by dogs. Ten deaths occurred from rabies. The cost and inconvenience of local treatment and immunization of this large group of people deserve serious consideration. Even if the disease were not a fatal one, the fact that 18,466 people were reported bitten should arouse public sentiment favoring the control of dogs. The compilation of adequate statistics for

V.: Experience with Canine Antirabic Vaccine, Canine-Feline Practice, published by North American Veterinarian, Jan. 12, 1928. The value of inoculation even under these circumstances is questioned by some authors; e. g., Barnes, M. F.; Metcalf, A. N.; Martindale, W. E., and Lentz, W. J.: Canine Rabies: Experimental Vaccination, Am. Vet. A. 84: 740 (May) 1934.
2. Manual for Health Officers, State of Illinois, Dec. 31, 1935.

3. Olsen, Robert: The Control of Rabies in New York City, Pub. Health Rep. 50: 1087 (Aug.) 1935.

4. McKendrick, A.: Fifth Analytical Review of Reports from Pasteur Institutes on the Results of Antirabies Treatment, Quart. Bull. Health Organ. 3: 613-653 (Dec.) 1934.

the United States on dog bites and on loss of life by man and animal from rabies transmitted by dogs should be the basis for a campaign of public education. The result of such education would be the eradication of rabies.

COMMENT

All bites by animals should be regarded with suspicion. The animal should be kept under observation

Fig. 5.—The wide-eyed stare during a rabic convulsion.

for a length of time sufficient to allow clinical and laboratory diagnoses to be made. Stray dogs and cats have no place in a civilized social order.

Wounds made by the bites of animals should immediately be cauterized with nitric acid. The Pasteur treatment or one of its modifications should be instituted in accordance with rules outlined and accepted.

The twelve persons whose case reports are included died after suffering great agony and might have been saved if adequate prophylactic measures had been instituted immediately. All were infected by dog bites. Stringent enforcement of regulations governing ownership, licensure, muzzling and leashing of dogs would have prevented the bites.

Fig. 6.—The bloody drooling and facial expression accompanying the pharyngeal spasm of rabies. Note the hand on the throat. This is characteristic.

The extent of this problem is evidenced by the fact that in the state of Illinois alone 18,466 dog bites were reported to the state department of public health in 1936 and that there were ten deaths from rabies. A knowledge of similar facts would divulge a tremendous loss of time and of lives of human beings and animals in the United States from a preventable cause. When such knowledge becomes public it will be of inestimable educational value in the eradication of this dreadful malady.

TYPHOID PYELONEPHRITIS, RENAL TYPHOID FEVER

HOBART A. REIMANN, M.D.

PHILADELPHIA

The typhoid bacillus like other members of the Eberthella group of bacteria is usually associated with disease of the intestinal tract, yet many instances occur wherein it localizes and causes infection elsewhere in the body. The frequency with which typhoid bacilli invade the blood during typhoid fever accounts for their dissemination to other parts of the body, and when localization does occur elsewhere it is usually regarded as a complication. Serious diagnostic problems arise when the bacilli attack vital areas like the meninges, the lungs or the kidneys, especially if intestinal symptoms are minimal or absent, as they sometimes are. Etiologic diagnosis under these circumstances is of especial importance, since patients with typhoid pneumonia or typhoid renal infection are dangerous as disseminators of infection and their excretions may spread typhoid bacilli widely unless proper measures are used to disinfect the sputum or urine before disposal. In the case of typhoid renal infection, etiologic diagnosis is apt to be missed unless careful differential bacteriologic tests are made. Since the colon bacillus, which closely resembles the typhoid bacillus, is by far the commonest cause of pyelitis or pyelonephritis, gram-negative bacilli found in purulent urine may be dismissed as colon bacilli in routine laboratory diagnosis if no further study is made. Other gram-negative bacilli may also cause infection of the urinary tract. Neter¹ recently collected fourteen cases of infection caused by *Bacterium dysenteriae* and added three cases of his own in which symptoms arising from the intestinal tract were absent. The important point to emphasize in infections of the urinary tract, as with infections of the respiratory, digestive and other systems, is that diagnostic anatomic terms such as pyelitis or pyelonephritis are no longer sufficient. It is necessary for purposes of preventive medicine and specific therapy to establish etiologic diagnoses by bacteriologic methods in every case and to employ such terms as colon bacillus pyelitis, pneumococcus type XIV pyelonephritis or typhoid pyelonephritis as the case may be.

According to Patch,² typhoid infections of the kidney are more common than has been generally believed. In one series of cases³ pyuria was present in 17 per cent of cases of typhoid fever. MacKenzie⁴ recovered *B. typhosus* and *B. paratyphosus* four times among 468 samples of catheterized urine. The typhoid lesions most commonly found in the kidney are acute bilateral cortical and interlobular areas of suppuration with pyelitis, ureteritis, cystitis and perinephric abscess. Chronic pyonephrosis may result. The onset of the renal infection may occur during an attack of typhoid, during convalescence or at a later date, sometimes many years afterward. In certain cases there may be no history or clinical or pathologic evidence of intestinal involvement at all.

Typhoid pyelonephritis or renal typhoid, with which this paper deals, is an uncommon complication of typhoid fever, and is rarer still as a primary disease without evidence of intestinal infection. Posselt⁵ was able to find only one report of an authentic case with necropsy in which the disease was limited entirely to the kidney without symptoms or other evidence of intestinal infection. He cites three other cases in which clinical studies alone were made. In the present case report another patient with bilateral typhoid pyelonephritis is described in whom no evidence of intestinal typhoid fever was present.

REPORT OF CASE

History.—A youth aged 17 lived in Bristol, Pa., but went to work on a farm in July 1937, where he drank water from a pump. He stated that the urine began to be dark or reddish about August 5. About a week later he noted the gradual onset of headache and pains in the back, legs and arms. August 15 a chill occurred, followed by sweating, and he felt ill enough to go to bed. Chills recurred daily for three days. He had several nosebleeds. He was admitted to the hospital August 19, probably about the eighth day of illness, with a fever of 39.4 C. (103 F.) and a pulse rate of 96.

Fig. 1.—Record of the temperature, pulse rate, blood pressure and non-protein nitrogen of a patient with typhoid pyelonephritis.

He did not remember ever having had typhoid fever, venereal infection or other serious illness but had usually enjoyed good health. The patient was well developed but drowsy and obviously very ill. The pharynx was reddened. The heart and lungs were normal. The blood pressure was 113 systolic and 70 diastolic. There were marked tenderness and protective rigidity in the right upper quadrant of the abdomen. The spleen and liver were not palpable because of the rigidity. There was tenderness in the right lumbar region posteriorly. The red blood cells numbered 3 million, the leukocytes 5,800. The hemoglobin content was 60 per cent. There was slight albuminuria, the specific gravity of the urine was 1.002, and 200 leukocytes and a few erythrocytes were present in a high power microscopic field in an uncentrifuged sample. The total quantity of urine in twenty-four hours was 1,500 cc.

The intern suspected (1) pyelonephritis of the right kidney, (2) typhoid fever and (3) subacute bacterial endocarditis. A culture was then made of a sample of urine and a pure growth of *B. typhosus* was recovered, but the Widal reaction and blood culture were negative. The nonprotein nitrogen measured 123 mg., the creatinine 7 mg. A diagnosis of typhoid pyelonephritis was made.

The patient's condition remained about the same for several days, except for repeated vomiting and an increase in the amount of nonprotein nitrogen as shown in figure 1. The temperature

then declined and he felt and looked better. On the seventeenth day the condition became worse, although the temperature remained low. A transient erythematous eruption, believed to be toxic in origin, appeared over the extensor surfaces of the arms, legs and back. The output of urine varied between 1,500 and 2,000 cc. a day, increasing to 2,500 and 3,000 cc. after the seventeenth day, and many red blood cells were present. The amount of nonprotein nitrogen in the blood rose to 205 mg. and the creatinine to 9.6 mg. The patient was more stuporous and appeared to be approaching a uremic state. The blood pressure did not rise. A few rose spots appeared on the abdomen. He was given dextrose solution intravenously.

The temperature rose again to higher levels on the twenty-fifth day and remained high for ten days, as shown in the chart, but the patient slowly improved clinically. The amount of nonprotein nitrogen in the blood gradually returned to normal. The systolic blood pressure, surprisingly, was never elevated, except on one occasion when it was 130; the diastolic pressure dropped to 50. There was no edema. The ocular fundi showed no abnormalities. A pyelogram after the intravenous injection of an opaque iodized substance (skioidan) was made on the thirty-fourth day. Both kidneys appeared to be normal in size and shape. The substance was too faintly visible to determine the shape of the calices of either kidney. The bladder after one hour was faintly discernible. Albuminuria, pyuria and hematuria persisted, and in tests on the thirty-ninth day the output of phenolsulfonphthalein was 45 per cent and the urea clearance test 52 per cent of normal. Typhoid bacilli were present in most samples of urine until the fifty-fifth day. The urea clearance test on the sixty-sixth day showed improvement up to 83 per cent clearance. No granular casts were seen until the seventieth day. The blood leukocytes never exceeded 9,500 and the erythrocytes averaged about 3 million. The Widal test and blood culture were never positive.

After the forty-second day the temperature gradually declined and reached normal on the forty-eighth day. The patient improved, but hematuria, cylindruria and pyuria persisted. On the fifty-second day another pyelogram revealed that the opaque substance appeared in the kidneys five minutes after intravenous injection, but the shadow did not become dense as would be expected normally. The pelvis and calices of both kidneys appeared normal in shape. The ureters were catheterized by Dr. David M. Davis on the sixty-third day, and pus and blood were found in the urine from both kidneys. Cystoscopy showed no evidence of obstruction or anomaly. The bladder wall was normal.

The problem of therapy with mandelic acid was considered early in the illness, but the drug was not given then because of the possible danger of aggravating the severe renal infection. Later, when the acute stage had passed and because of the persistent typhoid bacilluria, syrup of mandelic acid 10 cc. four times a day was given on the sixty-fifth day and continued for two weeks. Cultures made of the urine after this time were sterile. The patient resumed good health but albuminuria from 20 to 60 pus cells per high power microscopic field and hyaline and granular casts were present in the urine when the patient was discharged November 14, ninety-five days after the onset of his illness.

Follow-Up Study.—The patient was induced to reenter the hospital for study in June 1938, ten months after the onset of his illness. Since leaving the hospital in November he had resumed his usual mode of life, but in April he left school one day feeling feverish. He had two shaking chills several hours apart and a temperature of 38.9 C. (102 F.). The urine at the time became a dark brownish red. After three days in bed he recovered. No studies were made of this illness, which presumably was a recurrence of his renal infection. When he was reexamined in June no abnormalities were found other than the laboratory data. The temperature and pulse rate were normal; the blood pressure was 100 systolic and 75 diastolic. The weight was 64 Kg. (141 pounds). The amount of urine per day varied from 1,000 to 1,500 cc. The specific gravity in two concentration tests was rather fixed and varied from 1.010 to 1.018. Albuminuria (1+), granular casts and red blood cells were present in all samples examined. Leukocytes were

5. Posselt, Adolf: Atypische Typhusinfektion: Typhus ohne Darm-erkrankung (Extraintestinale Typhuslokalisationen mit spezieller Berücksichtigung der primären Typhosen Gallenwege und Leberprozesse), *Ergebn. d. allg. Path. u. path. Anat.* 16: 184-340 (1. abt) 1912.

present in normal numbers. Four samples of urine were sterile on culture. The urea clearance was 84 per cent of normal and the urea nitrogen of the blood measured 16 mg. The plasma proteins totaled 8.5 mg., of which 4.7 was albumin and 3.8 globulin. A pyelogram made after the intravenous injection of an opaque substance showed no abnormalities. The hemoglobin was 70 per cent and the red blood cells numbered 4,100,000. The ocular fundi were normal. Cultures of the feces and duodenal contents were negative for *B. typhosus*.

Several peculiarities stand out with regard to the diagnosis of pyelonephritis; the blood pressure did not rise perceptibly, although the blood metabolites were greatly increased and roentgenographic and other evidence of diminished function of the kidneys were present; casts did not appear in the urine until the seventieth day, and no changes were noted in the eyegrounds. Nevertheless all other evidence, including the uremic symptoms and the results of ureteral catheterization, indicated the existence of bilateral pyelonephritis.

The question may be raised as to whether the case can be considered to be of "primary" typhoid pyelonephritis. In addition to the systemic symptoms of typhoid fever, evidence of renal insufficiency and pain in the right lumbar region pointed to a localization of the infection in the kidneys almost at the beginning of the disease. Dark urine was actually noted by the patient before the onset of clinical symptoms, but reliance on his observation is uncertain. It is probable that the patient was infected by drinking contaminated water on the farm and that the bacilli entered the blood from some place in the intestine. Flexner⁶ believed it possible for typhoid bacilli to pass through the bowel wall into the blood without leaving a lesion, but it is very likely that in most cases renal infection is secondary to a lesion at the portal of entry in the bowel no matter how trivial or symptomless the latter may be. There is no evidence in the case described here that the intestine was ever involved in an inflammatory reaction, since diarrhea was not noted and blood and typhoid bacilli were never found in the feces. Controversy on this point, however, is unimportant. The important fact is that the kidneys may bear the brunt of a typhoid infection regardless of the portal of entry or pathway of infection, and the symptoms of pyelonephritis may dominate the illness.

As to the mode of infection of the kidneys, it is generally believed to be, and most likely is, blood borne. Infection is especially liable to occur during bacteremia if the kidney is not normal, that is if any factors such as stone, trauma, hydronephrosis, congenital anomaly or other conditions are present to cause obstruction to the flow of urine. Hematogenous infection usually results in disease of both kidneys, and the lesions are found in the cortex and medulla since both areas are supplied with blood by branches of the arcuate artery as shown in the inset in figure 2. Another route of infection to the right kidney is said to exist in the communication

of the lymphatics between the ascending colon and the capsule of the kidney (fig. 2), which may be of particular importance in typhoid fever or other enteric disease. There is also known to be a communication between the lymphatics of the kidney substance with those of the fatty capsule (inset *a*, fig. 2). This communication may account for the occasional development of perinephric abscess in typhoid fever. After infection becomes established in the kidney it may spread from place to place by way of the meshwork of lymphatics around the tubules and glomeruli, extending from the tip of the papilla to the capsule. It is conceivable that the involvement of much of the renal substance may

Fig. 2.—Schematic diagram of possible pathways of infection to the kidney. The lymphatic connection between the ascending colon and the capsule of the right kidney is shown. The arterial system in inset *a* shows how hematogenous infection may occur in any portion of the kidney and how it may spread by way of the network of lymphatics which extend from the tip of the papilla through the kidney substance and communicate with the lymphatics of the renal capsule. (Reproduced by courtesy of Lea & Febiger from chapter XX, *Infections of the Kidney* by H. A. Reimann in *The Kidney in Health and Disease*, Hilding Berglund and Grace Medes, 1935.)

eventually lead to permanently damaged secreting tissue as genuine interstitial nephritis, resulting in the so-called schrumpfnier, or granular contracted kidney.

SUMMARY

In a case of typhoid pyelonephritis presenting systemic symptoms and signs of typhoid fever lasting forty-seven days, the clinical features were remarkable in that no symptoms referable to the intestinal tract were noted. The main interest centered about the typhoid state with threatened uremia and evidence of retention of metabolites, typhoid bacilluria, pyuria,

6. Flexner, Simon: Certain Forms of Infection in Typhoid Fever, *Johns Hopkins Hosp. Rep.* 5: 343-378, 1895.

hematuria and pain in the right lumbar region, which were present as early as the eighth day of illness. The patient recovered, but pyuria, bacilluria and hematuria persisted. Typhoid bacilli disappeared from the urine after the administration of mandelic acid. Evidence of active renal disease ten months after the acute attack supports the growing mass of evidence that renal infections, particularly in childhood, must be looked on as a cause of subsequent kidney disease.⁷ Whether chronic nephritis and hypertension will eventually develop in this case can be determined only by future examination.

It is important to establish etiologic diagnosis promptly in all cases of acute or chronic pyelonephritis, since there is no doubt that patients like the one described may serve as a dangerous source of infection to others if proper precautions are not taken to sterilize the urine before its disposal.

Jefferson Hospital.

THE USE OF SERUM IN THE TREATMENT OF THE HIGHER TYPES OF PNEUMONIA

NORMAN PLUMMER, M.D.

NEW YORK

When the thirty-two types of pneumococcus were first described by Cooper, Edwards, Rosenstein, Walter and Peizer,¹ the work was considered highly academic and of little practical significance. However, chiefly because antipneumococcus serum is still the only specific therapeutic agent proved to be useful in the treatment of pneumonia and because all attempts to prepare a nonspecific or a polyvalent serum have failed, the separation into the higher types has become increasingly important. Only two of the original thirty-two types have been dropped: type XXVI, cross agglutinating with type VI, and type XXX, cross agglutinating with type XV. The remaining thirty types account for over 99 per cent of all strains of pneumococcus.

Table 1 was prepared to show the relative incidence of the more frequent types of pneumococcic pneumonia of adults. Seventy-eight per cent of 6,545 cases studied in New York, Boston, Cincinnati and San Francisco by Bullowa,² Finland,³ Benjamin, Blankenhorn, Rueggesser and Senior⁴ and Kohl and Reitzel,⁵ occurred in eight of the specific types. Type I pneumonia stands by itself as the most common, but types II, III, V, VII and VIII had a surprisingly similar incidence in this large series. It is noteworthy that the higher types cause

over 50 per cent of all pneumococcic pneumonia. Preparations of concentrated serum for types IV, V, VII and VIII, as well as for types I and II, have already been accepted by the Council on Pharmacy and Chemistry. In addition, serum is at present being used for types III, VI, XIV and XVIII, and within a short time serum will have been prepared for all thirty types.

This report is presented to give my experience and that of my associates with concentrated serum in the treatment of pneumonia due to the pneumococcus of types other than I and II. In the ten year period 1928 to 1938, 561 cases of pneumonia of types other than I, II and III were studied, 492 at Bellevue Hospital and sixty-nine at New York Hospital. The distribution of the different types and the number of deaths from each type are given in table 2. One hundred and eleven of the patients received specific antipneumococcus serum. In addition, during the last year nine patients with type III pneumonia were treated with rabbit antipneumococcus serum. In 145 cases of the less frequent types there were thirty-eight deaths (26 per cent).

The methods of treatment have changed from time to time, following a trend to procure more rapid typing and to treat the patients earlier.

Typing in the earlier cases was done by the mouse method of Avery, but this was soon supplanted by Sabin's slide agglutination method, and in the past five years the Neufeld method, as described by Sabin,⁶ has been the one principally used. By this procedure the diagnosis was made in a good proportion of the cases within one hour of the time at which typing was instituted. Specimens other than sputum, such as material swabbed from the throat, blood for culture, spinal fluid and pleural fluid, were also studied by the Neufeld

method. In some instances preliminary cultures and other modifications of the method were necessary. Most of the type determinations were repeated at least once before the final diagnosis was made, although the use of serum was usually started after the first report. In most of the cases at least one blood culture was made. Punctures of the lung were performed in only a few of the cases, because of the possible complications of this procedure.

The mode of administering serum also was changed a number of times during the ten year period, chiefly because of improvement in the preparations used. The first patients were treated with unrefined horse serum, which produced reactions with most injections and which necessitated divided doses of serum. Methods

* Includes cases in which serum was used and cases in which it was not used.

taken. A fresh preparation of epinephrine, 1:1,000, should always be at hand. The history should be taken, because it occasionally reveals the only clue for discovering an allergic state. Both the ophthalmic and the intracutaneous test, in our experience, have been found valuable as preliminary tests for sensitivity. A positive ophthalmic test with a 1:10 dilution of whole serum is considered a contraindication to the use of serum. A positive intracutaneous test is not a contraindication to the further injection of serum but serves as a warning against a possible allergic reaction. It is true that a good percentage of the patients with a positive intracutaneous test can take serum intravenously without any further sign of reactivity. The intracutaneous test with rabbit serum has been found to be just as reliable as that with horse serum.

After the two tests, our present routine is to give 0.1 cc. of therapeutic serum intravenously. If there have been no untoward reactions after one and a half hours, either 1 cc. or 5 cc. is given, the dose depending on the preparation used and the patient being treated. The third dose is given one and a half hours after the second injection and is either the remainder of the full estimated dose or the largest amount that it is believed the patient will tolerate without a reaction. Experience has shown that the massive injection is preferable to a divided dose; however, reactions should be prevented. It has been demonstrated that chills and other reactions can frequently be avoided by giving the serum in gradually increasing amounts. We feel that the thermal reactions are harmful rather than beneficial to patients with pneumonia, and our method of administration has always been planned to avoid as many reactions as possible. Our experience in giving acetylsalicylic acid and other drugs before the injection of serum as a prophylactic measure against thermal reactions has not been favorable.

Our investigation shows clinical and statistical evidence of the value of concentrated serum in the treatment of the pneumonias of the higher types. Many patients with pneumonia of a higher type, particularly of type IV, V, VII, VIII or XIV, which types are seen most commonly, show a clinical response to early serum treatment similar to that noted in patients with type I

pneumonia. The temperature drops rapidly, very much as in a normal crisis, and all symptoms of toxemia frequently disappear within twenty-four hours of the institution of treatment. In addition, the effect on bacteremia seems to be as marked as that described with type I serum. The accompanying charts show the clinical course of patients treated early with an adequate amount of potent serum. Chart 6 shows the striking clinical effect of rabbit antipneumococcus serum of type XVII in a case of postoperative pneumonia.

The results of treatment with specific serum on the mortality rates for pneumonia of types IV, V, VII, VIII and XIV in 104 cases are shown in table 3. A reduction in the mortality rate is noted for types IV, V and VIII, and there is a slight lowering of the percentage for the entire series. These figures are not very striking, and one must refer to the larger series of collected cases in order to formulate any opinion on this subject. Heffron⁷ has recently collected from the literature all the cases of these more frequent higher types. This series is also shown in table 3. A reduction in the number of deaths is noted for all the types except type IV, for which the number of cases is so small that the results may be misleading. A striking effect is noted for types V, VII and VIII, and the reduction from 27.2 per cent to 16.9 per cent in the mortality rate for the total series of 563 cases is also definite.

COMMENT

The present investigation, together with figures obtained from similar studies,⁸ emphasizes the significance of pneumonia caused by the higher types of the pneumococcus. The mortality rates for these types, while not as high as those for types II and III, are sufficiently high to indicate the severity of the infections. The incidence of the more frequent of the higher types

is almost the same as that of types II and III; the rarer types when grouped together still account for a good number of cases of pneumonia. It is important however that, when the thirty diagnostic serums are used, less than 1 per cent of pneumonias are unclassified.

Perhaps the greatest advance in the past few years as far as pneumonia is concerned is the greater appreciation by the medical profession and various community and public health organizations of the seriousness of this disease and the potentialities of serum and other prophylactic measures in its control. Many states and communities are now supporting expensive pneumonia

VII, VIII, XIV and XIX. It should be pointed out that the incidence will be higher in such a study when the carrier types, such as types III, VI, VIII and XIX, are included than when only proved pneumonias are studied.

Although the total number of cases in our study is impressive, when the cases in which serum was used are distributed through the different types, no group is large enough to permit us to draw any definite conclusions. The statistical results for types IV, V, VII and VIII compared closely enough with the results in similar series to be significant. Certainly enough cases of serum-treated pneumonia of types V, VII and VIII can now be collected from the literature to show that the mortality rates for these types can be definitely reduced. Collected cases of type IV and type XIV pneumonia show only suggestive figures. As far as the remaining higher types are concerned, so few patients have been treated with serum that a statement as to the effect on fatality rates cannot be made. However, since the introduction of rabbit serum quite a number of the whole group of patients have been treated and the impression gained so far is that most types of pneu-

control programs—supplying antipneumococcus serum, establishing pneumococcus typing stations and promoting extensive educational projects. It can be said that pneumonia has entered the sphere of public health medicine, and it is hoped that public health methods will be as effective in controlling this disease as they have been with such infections as diphtheria, typhoid fever and tuberculosis.

The Massachusetts state, New York city and New York state pneumonia control services have already published the results of some of their studies. The New York city⁹ and the Massachusetts state¹⁰ services have

Chart 3.—Temperature curve, result of blood culture, and leukocyte count, case 3.

monia respond to serum. Certainly, the large experience with serum in the treatment of the most frequent types, together with the extensive experimental background, would lead one to predict that favorable results will be obtained with all types for which a potent serum can be produced.

Postoperative pneumonia in the past has been differentiated from so-called medical pneumonia. It has been considered "atypical pneumonia" or "group IV pneumonitis" and usually has been treated without bacteriologic study. It is true that in many cases it runs a mild course, but it is also true that postoperative pneumonia has a rather high fatality figure. With the thirty diagnostic serums it is now possible to discover the specific infecting organism in many cases. The prompt use of serum, it seems certain, will save lives and will also shorten the course and lessen the severity of the complication. Chart 6 shows an excellent clinical response with rabbit antipneumococcus serum of type XVII in a young woman in whom acute pneumonia developed after appendectomy.

The importance of type III pneumonia and the interest in the serum treatment of this very fatal disease seem

presented figures showing the distribution of the thirty-two types of pneumococcus in the sputums studied. The cases reported are of pneumonia as well as of suspected pneumonia, and they show an even larger incidence of the higher types, particularly types IV, V,

to justify a brief report of our limited experience with rabbit antipneumococcus serum of type III. Because of the severe reactions produced by the concentrated product, it was not possible to make any sort of a trial until recently, when it finally became possible to refine and concentrate rabbit serum so that only occasional reactions occurred and a highly potent product could be utilized.

We have treated nine patients with type III concentrated rabbit serum, the last six having had no untoward reactions. Of the nine, three died and six recovered. Of those who recovered, one had a positive blood culture when serum treatment was instituted. Three were treated very early in the course of the disease and showed prompt response to a large unitage of serum. Chart 7 shows the course of an elderly patient, with definite signs and with an unfavorable outlook at the onset, who responded promptly to very early treatment with serum. Our experience is too meager to indicate any positive conclusions. However, our most recent results, together with the report of MacLeod and his associates,¹¹ who at the Rockefeller Institute Hospital have now treated fourteen patients with type III pneu-

of 3.7 per cent. Bennett¹³ recently reported 100 cases of pneumonia of five types, not including type III, treated with rabbit serum, with a mortality rate of 7 per cent. Both of these reports are extremely encouraging but are based on a comparatively small series of cases. It is too early therefore to formulate any opinion as to the relative efficiency of the two serums.

Chart 4.—Temperature curve, result of blood culture, and leukocyte count, case 4.

monia with four deaths, lead us to hope that with a serum high in antibody, given shortly after the onset, there will be definite favorable response.

Antipneumococcus rabbit serum has taken the focus of attention recently, but whether rabbit serum, unit for unit, is more effective than horse serum remains to be proved. Certainly with rabbit serum it is possible to obtain a preparation high in antibody against type III pneumococcus and against a few of the rare types for which no potent serum was possible with the horse product. Furthermore, it is possible to prepare rabbit serum against the rarer types more economically. However, with the types for which a potent horse serum has been available, in our experience the response with it has been just as satisfactory as that with the rabbit product. Early treatment shows striking results with both. Horsfall and his colleagues¹² at the Rockefeller Institute, in their most recent report on the use of rabbit antipneumococcus serum, presented fifty-four cases of nine types, excluding type III, with a mortality rate

Chart 5.—Temperature curve, result of blood culture, and leukocyte count, case 5.

SUMMARY AND CONCLUSIONS

Pneumonia of the higher types is an important part of the pneumonia problem. In a collected series of 6,545 cases of pneumococcal pneumonia, over 50 per cent of the cases were of the higher types, 30 per cent being of types IV, V, VII, VIII and XIV.

Antipneumococcus serum was used in 111 cases, with a rather marked clinical response and an appreciable effect on the mortality rate for the combined series of cases of pneumonia of types IV, V, VII, VIII and XIV. At present there are available refined and concentrated preparations of horse and of rabbit serum that are

Chart 6.—Curves for temperature, pulse rate, respiratory rate and leukocyte count, case 6.

high in antibody content and almost entirely free from reaction-causing substance. With such products the prospects are excellent for obtaining increasingly better results in the treatment of all types of pneumococcal pneumonia.

REPORT OF CASES

CASE 1 (chart 1).—The sputum of J. H., a woman aged 45, admitted to New York Hospital on the third day of her illness, showed type IV pneumococci. Blood taken on admission showed a positive culture in the broth and a negative culture on the agar plate. On the day following admission, before treatment with serum was instituted, the blood culture was again positive. On that day, the fourth day of illness, after the routine tests for sensitivity, 192,000 units of concentrated type IV horse serum was administered intravenously. Early the following day 104,000 units of the same preparation was given. A total of 296,000 units was given in a twenty-eight hour period in seven injections without any reaction. The blood culture on the fifth day was negative. The temperature dropped to slightly above normal on that day, and from that time the patient made an uneventful recovery. This patient received nearly 300,000 units of serum because of the severity of the toxemia, the bacteremia and the tardiness of the treatment.

CASE 2 (chart 2).—The sputum of F. G., a man aged 41, admitted to New York Hospital seventeen hours after an acute onset, showed type VII pneumococci. A culture of blood taken on admission was positive. On the first day, because of particularly severe toxemia and because of almost complete involvement of the right lung, the patient received 213,200 units of type VII horse antibody. The following day, because the temperature was still elevated and the blood culture was reported positive, 210,000 units more was administered. After this

day with 200,000 units of rabbit serum. Moderate chills occurred after three of the eight injections. The abrupt drop in the temperature was probably accentuated by the thermal reaction to the serum. The blood culture was sterile on the day after the serum was given. The convalescence was rapid.

CASE 6¹⁴ (chart 6).—D. R., a woman aged 23, showed symptoms of pneumonia twenty-four hours after appendectomy. She had signs of consolidation of the left lower lobe and a leukocyte count of 19,000. The sputum showed a pure culture of type XVII pneumococci. Treatment with concentrated rabbit anti-pneumococcus serum of type XVII was instituted six hours after the onset of acute respiratory symptoms. The patient received 255,000 units intravenously within twelve hours without any untoward reactions. The temperature and the pulse and respiratory rates dropped promptly. The recovery from pneumonia was rapid. A large amount of serum was given on account of the preceding operation and the acute toxemia and because this was our first experience with type XVII serum.

CASE 7¹⁵ (chart 7).—The sputum of C. A. G., a man aged 72, showed type III pneumococci. Signs of consolidation of the right lower lobe developed. Treatment with type III concentrated rabbit serum was instituted twelve hours after onset, and 218,300 units was given in a twenty-four hour period in six injections without any reactions. The temperature dropped, and the symptoms of toxemia subsided promptly.

ABSTRACT OF DISCUSSION

DR. E. L. BORTZ, Philadelphia: The treatment of types I and II pneumococcus pneumonia has proved the value of specific therapy so completely that it is generally accepted now as the standard procedure by all investigators in this field. Because of the importance of early diagnosis, pneumonia should be regarded as one of the great medical emergencies. In Pennsylvania the mortality rate from pneumonia is ten times that from appendicitis. The prevalence of types I and II caused attention first to be centered on these. Now that specific treatment for these two types has proved effective, it is logical to study its utility in the so-called rarer forms. The only way to determine the frequency of occurrence of the various types of pneumonia is to make a bacteriologic diagnosis on every patient suspected or afflicted. The Neufeld method of typing is so simple that technicians can readily determine the disease. Indeed, interns in many hospitals do their own typing. To ascertain the frequency of occurrence of all types it is necessary to test the specimen not only for organisms of types I and II but for organisms of the other twenty-eight types as well. Cooperation of doctors and health authorities is essential if pneumonia is to be brought under control. The nature of the problem lends itself to an approach on a broad geographic plan. In Pennsylvania 131 typing centers have been set up by Dr. Edith McBride Dexter, state secretary of health, where diagnostic facilities are available to doctors twenty-four hours a day. We hope to find out much about the various types of pneumococci, especially as to their occurrence. Then we want to watch their fluctuations from time to time. The treatment of the higher types will adjust itself along established lines. In Pennsylvania, serum treatment for types I, II, V, VII, VIII and XIV is beyond the experimental stage; we have therefore made these type serums available to every doctor in the state. But before he can get the serum he must first have made a bacteriologic examination. Through the generous assistance of one of the large pharmaceutical houses, treatment serums for other types has been furnished to certain clinicians in Pennsylvania for further investigation. It appears that except for type III, and even with this type in patients under 45 years of age, specific serum therapy gives some success in treating the rarer types.

DR. BYRON F. FRANCIS, Seattle: Dr. Plummer's paper is important. We who work in smaller places must depend on such controlled statistical studies in order to evaluate the effectiveness of any therapeutic procedure. However, if the physicians and hospitals of smaller communities were organized

Chart 7.—Temperature curve, case 7.

intensive treatment the blood culture became negative and the toxemia subsided. The convalescence was uncomplicated except for mild serum sickness.

CASE 3 (chart 3).—The sputum of A. G., a woman aged 37, admitted to New York Hospital four hours after an acute onset, showed type VII pneumococci. A blood culture was negative. On account of acute toxemia, extensive signs in the left lung and a very high leukocyte count on the second day, 240,000 units of type VII horse serum was given. The temperature showed a critical drop, and recovery was prompt except for mild serum sickness. Since treatment was begun early and the disease was uncomplicated, the patient probably received more serum than was necessary.

CASE 4 (chart 4).—The sputum of J. K., a man aged 58, admitted to New York Hospital on the second day of acute illness, showed type VIII pneumococci. A culture of blood taken on admission was positive. The patient received 188,800 units of concentrated type VIII horse serum within thirty-six hours. There were no immediate reactions. The toxemia subsided promptly. The convalescence was uncomplicated except for serum sickness, which became acute on the seventh day, causing a temporary elevation in temperature and leukocyte count.

CASE 5 (chart 5).—The sputum of M. J., a man aged 29, admitted to New York Hospital on the third day of acute illness, showed type VIII pneumococci. Blood taken on admission showed a positive culture in the broth and showed five colonies on the plate. The patient was treated on the fourth

14. Permission to report this case was given by Dr. W. H. Lohman, Brooklyn.

15. Permission to report this case was given by Dr. S. A. Garlan, New York.

to pool their individual experiences it might be possible to compile useful information of this sort. Clinical impressions are likely to be unreliable. The idea has prevailed that pneumonia is a relatively benign disease in the Pacific Coast region and that lobar pneumonia takes an atypical course. However, the few available series from this region which have been studied do not confirm this impression. When the course of pneumococcal pneumonia is carefully studied clinically and roentgenologically in a large number of cases, one finds that a great percentage do not conform to the classic picture of lobar pneumonia. The disease apparently takes a greater variety of clinical forms than was previously realized. The pneumonias should be classified on a bacteriologic and immunologic basis rather than according to the anatomic form. Correct typing is important but sometimes difficult, especially when material for typing is scanty. The typing should be checked frequently, especially if the expected response to serum is not obtained or the first reaction reveals one of the so-called carrier types. The agglutination test has been useful for determining when the administration of serum should be discontinued. If a positive agglutination test is obtained with undiluted serum, one may assume that an overabundance of antibodies is present.

DR. PHILIP G. CORLISS, Somerton, Ariz.: I practice in a small town near Yuma, Ariz., and am probably representative of the physicians of the small towns. We work under a disadvantage because the people are poor. It is an agricultural community, and the serum is very expensive. In the past two years I have treated every case with serum and have not lost a case. My experience with the higher types has been limited almost exclusively to type VII. I want to ask a question as to the amount of serum to be given in a case. Dr. Blankenhorn stated that he never gave more than 200,000 or 300,000 units. I had a case of type VII which I believe we would have lost if we stopped at 300,000. We pulled the patient through with 420,000. I want to ask Dr. Plummer about mixed infections. He has not mentioned any cases of mixed types. I have had two cases of type VII. In one case, type VII and type I pneumococci were found; in the other case of type VII also type II pneumococci was found. Both responded favorably to the serum.

DR. WILLIAM C. BRUFF, Whittier, Calif.: In the Los Angeles General Hospital we have been using serum for several years. I wish to make one point with regard to the use of the agglutination test as a test of adequate treatment. My impression is that we might as well throw that test out. We have seen, in spite of the presence of complete agglutination, the disease spread to new lobes and the patient go downhill and die. We have repeatedly seen good recovery, clinically, in the absence of any agglutination. I think one is much safer to follow the clinical signs and continue the serum until there has been a good drop in pulse and temperature or until one has exhausted one's resources of serum and have given up. I should like to ask what the author considers the limit of serum dosage in late and unfavorable cases. How far would he go in giving serum?

DR. NORMAN H. PLUMMER, New York: Since pneumonia has entered the field of public health medicine, a great deal has been accomplished. The cost of serum has always presented a serious problem. Now serum is being furnished by some of the states, making it possible to treat the patients with adequate amounts. In the states of New York and Massachusetts, comprehensive pneumonia control programs have been established. A question was asked regarding the dosage of serum in pneumonia. I agree that the clinical course is still the best guide to dosage. I have used both the slide agglutination test described by Sabin and the carbohydrate cutaneous test of Francis. Of the two, the Francis test has been found to be more satisfactory. Regarding the question of complications: In my experience complications have occurred with about the same relative incidence in the cases treated with serum as in the cases treated without serum. A mixed pneumococcal infection is occasionally discovered. Such a case usually shows one of the carrier types in addition to the infecting type. For example, if sputum shows type I and type VIII pneumococci, it can be assumed that the type I is the infecting organism and that the type VIII is a carrier

organism. The actual infection may be caused by more than one type, but the usual relationship of these organisms is the one already cited. In the cases of type III pneumonia presented in my paper, serum alone was used. In a smaller number of cases in which sulfanilamide alone was used, it was not possible to note beneficial clinical effect. Since seeing Dr. Osgood's demonstration of the bone-marrow culture medium, in which the combination of specific serum and sulfanilamide has such a striking effect on the pneumococcus, I am anxious to determine what clinical effect this combination will have. The following question has been asked: Some of the thoracic surgeons are treating pneumonia by position, sometimes standing the patient on his head, sometimes laying him on one side and then on the other, and sometimes changing his position three or four times daily. They claim that almost all pneumonias are due to a collapse of the lobe of the lung. Do you use the positions? In reply I would say No, I do not emphasize posture. My experience with postoperative pneumonia has indicated that most cases are cases of pneumococcal pneumonia and that they should be given the benefit of serum. I do not entirely subscribe to the idea that they are cases of atelectasis. They should be treated as pneumonia.

Clinical Notes, Suggestions and New Instruments

TRAUMATIC APPENDICITIS

C. M. BURGESS, M.D., HONOLULU, HAWAII

It is generally conceded, at least by industrial surgeons and insurance companies, that appendicitis of traumatic origin is a disease entity. Of course it is impossible to prove in the laboratory or by any other means that in a certain case acute appendicitis is traumatic in origin. However, in going over closely the history and clinical course of many cases reported in the literature as instances of traumatic appendicitis, one must admit that coincidence alone would be overtaxed to explain the phenomenon.

This case is not reported with the intention of either supporting or denying the existence of traumatic appendicitis. Most authorities will admit that trauma may be a contributing factor in the production of acute appendicitis in a previously diseased appendix. Since no organ in the body is immune to injury, no matter how deeply seated, it is not logical to say that appendicitis on a traumatic basis cannot occur in a previously normal appendix.

No attempt will be made in this report to review the literature on traumatic appendicitis. That has been so ably done recently by Maes and McFetridge¹ and by Shutkin and Wetzler² that further comment would be repetition. However, reading of the literature makes one thing apparent. For the cases reported as instances of traumatic appendicitis the mortality rate is extremely high. In Kelly's³ series of fifty cases it was 50 per cent; thirty-seven of the appendixes had ruptured or were gangrenous. In sixteen of the twenty-five fatal cases appendical involvement was unrecognized. In all subsequent series of cases the proportion is about the same.

Traumatic appendicitis is so rare that no one has a large series or becomes proficient in its care. But by physicians bearing the possibility of its existence in mind perhaps the mortality and morbidity of the disease process can be lessened.

The mechanism of traumatic appendicitis has not been satisfactorily explained. Gangrene and rupture predominate as a pathologic process, but no differentiation can be made from stained sections. The diagnosis must be made from the history and clinical course. The weight of opinion would indicate that the condition is due to a sudden change in intra-abdominal pressure which causes an influx of cecal contents past a narrowed

3. Kelly, H. A., and Hurdon, E.: Vermiform Appendix and Its Diseases, Philadelphia, W. B. Saunders Company, 1935.

portion of the appendical lumen. The distention and subsequent edema cause complete obstruction. Ultimate destruction results from rapid bacterial growth.

The patient, a man aged 46, a Hawaiian, was first seen about 10 a. m. May 21, 1937. Physical examination revealed that he was very well developed and well nourished and apparently in considerable pain. The right lower quadrant was extremely tender and rigid. The temperature was 101 F., the pulse rate 88 and the respiratory rate 23. The white blood cell count was 22,000, with 88 per cent polymorphonuclears. A diagnosis of acute appendicitis was made, and at operation a ruptured appendix found. The history is of great interest. For the previous two weeks the patient had been using a pneumatic drill to raise the ceiling of a tunnel through stone. This drill was suspended from the ceiling by means of a strap. To exert pressure he rested the butt of the drill in his right iliac fossa. About 10 a. m. May 20, 1937, while drilling, he suddenly had a pain in the right lower quadrant so severe that it doubled him up and prostrated him on the floor. This lasted several minutes, and, although it then became less severe, it prevented further use of the drill in the former position. A dull pain persisted until the next morning, when at work it became so severe that he was sent to a physician. There was no previous history of pain in the right lower quadrant.

The observations at operation were unusual. The cecum was attached unusually far toward the midline. The appendix was ruptured in such a way that the tip was amputated. It lay to the right of the cecum, sharply kinked upward at the base and directly over the psoas muscle. It was tightly bound to the posterior part of the parietal peritoneum by old tough adhesions at the region of the sharp kink upward. The peritoneum was drained. Convalescence was uneventful. Compensation was allowed.

This case seems to fulfil all the requirements necessary for the diagnosis of traumatic appendicitis. It is presented because of its rarity and because physicians cannot keep too much in mind a condition so high in mortality and morbidity.

INDUCED MALARIA IN A PATIENT WITHOUT A SPLEEN

REPORT OF A CASE

G. S. INGALLS, M.D., CINCINNATI

A patient was referred to the Cincinnati General Hospital for treatment of dementia paralytica with malaria. Familial hemolytic jaundice was a coexisting disease, which complicated the usual procedure. The existing moderately severe anemia was a contraindication to immediate inoculation with malaria. Splenectomy was therefore considered proper, so that the factor responsible for the excessive destruction of red blood cells could be removed.

The constant finding of splenomegaly in malaria suggested that some change might result in the reaction to malaria if the spleen were absent.

A review of the literature elicited no account of the course of this disease in a splenectomized subject. It was decided, therefore, to make certain clinical and laboratory observations on the course of induced malaria in this patient after splenectomy.

REPORT OF CASE

History.—D. H., a native-born American woman aged 31, a housewife, was admitted to the hospital July 23, 1937, after convulsions and transient attacks of hemiplegia.

The patient was in good health until 1933, when her skin became pale and faintly yellow. She lost strength and weight and was bedridden when a physician was called. His examination revealed a moderately enlarged spleen, 1,110,000 red blood cells, slightly increased fragility of the red cells and a strongly positive Wassermann reaction of the blood. Arsenical therapy for syphilis caused nausea and vomiting. The patient had been given approximately 500 intramuscular injections of a soluble

bismuth preparation during a three year period previous to her admission to this hospital. On Jan. 1, 1937, the patient began having epileptiform convulsions, followed by hemiplegia and aphasia lasting from two to three weeks. Potassium iodide and a bismuth compound were given rigorously during these episodes. Several similar attacks occurred before admission, and the last one was associated with increased jaundice. The patient's only complaint on entering the hospital was of a vague epigastric discomfort. Her mother and brother have familial hemolytic jaundice.

Examination.—On admission the patient was fairly well developed and nourished, anemic and not acutely ill. The temperature was 100.6 F., the pulse rate 106 and the respiratory rate 26. The blood pressure was 120 systolic, 68 diastolic. She weighed 96 pounds (43.5 Kg.). The scleras were slightly icteric. The pupils were regular and equal and responded actively to light and in accommodation. There were fine tremors of the lips and tongue. The speech was slurred and dysarthric. A firm, rounded, nontender spleen extended 6 cm. below the left costal margin. On deep inspiration the liver edge descended 4 cm. below the right costal margin. Soft, discrete, freely movable lymph glands the size of small peas were palpated in the groins, axillas and epitrochlear fossae. There were hyperactive deep reflexes and positive Hoffmann and Babinski signs bilaterally.

Laboratory examinations revealed a hemoglobin content of 60 per cent, 2,760,000 red blood cells, 9,500 white blood cells; neutrophils 74 per cent, lymphocytes 23 per cent, eosinophils 1 per cent, monocytes 2 per cent and reticulocytes 2.2 per cent. The bleeding time was two minutes and the clotting time five minutes. Clot retraction was complete within two hours. The fragility test of the red blood cells revealed that hemolysis began at 0.42 per cent saline and was complete at 0.34 per cent saline. The icteric index was 17.5. Total serum protein was 7.1 Gm. per hundred cubic centimeters. The blood uric acid was 4.2 mg. per hundred cubic centimeters. The Wassermann reaction of the blood was strongly positive. The cerebrospinal fluid was clear and colorless, was under 120 mm. pressure, gave a 2 plus Pandy reaction, showed 15 lymphocytes per cubic millimeter and gave a strongly positive Wassermann reaction and a colloidal gold curve of 5555543200. Urinalyses and stool examinations gave essentially negative results.

Mental Status: Friends and relatives had noticed no personality change. The patient was well kept and neat and spoke coherently. Her attention was easily held and she cooperated well. The dominant mood was cheerfulness, but she was unstable emotionally and cried easily. There were no delusions, illusions or hallucinations. Her fund of information, ability to calculate and judgment were moderately impaired. Memory for recent events was slightly defective. Her sexual desire was diminished.

A diagnosis of dementia paralytica and familial hemolytic jaundice was made. The patient was given a general diet and iron and ammonium citrates, 1 drachm (4 Gm.) three times a day. At the end of the second week the red blood cells had risen to 3,700,000. She was transferred to the surgical service and there was given 500 cc. of citrated blood intravenously before splenectomy was done. Operation and convalescence were uneventful.

After her return to the psychiatric ward her physical condition steadily improved. The fragility test revealed that hemolysis began at 0.55 per cent saline and was complete at 0.32 per cent saline. Serum carbon dioxide was 58.5 volumes per cent. Serum chlorides were 100.5 millequivalents per liter. Whole blood inorganic phosphorus was 4 mg. per hundred cubic centimeters. The patient received intravenous and intramuscular injections of blood from a patient with benign tertian malaria. Two days later the temperature, pulse rate and respiratory rate rose sharply to 102 F., 128 and 26, respectively. These elevations persisted, the values reaching 103.4 F., 134 and 30 before returning to normal at the end of seven days. Three days later a similar episode occurred, lasting five days. The temperature, pulse rate and respiratory rate reached 103.4 F., 120 and 30 and gradually fell to 99 F., 88 and 24. The white blood cells varied between 8,200 and 11,200. Urinalyses gave

negative results. Blood culture was negative. The Widal test was negative. Agglutination with *Bacillus melitensis* was negative. The Weil-Felix reaction was positive in a dilution of 1:320 and remained so during the patient's course in the hospital.

The patient had no complaints, and her physical condition was clinically unchanged from that on admission. On the sixteenth day after inoculation she began having paroxysms of chills and fever. A characteristic chill would be anticipated by the patient about one hour before its climax. She complained of malaise, chilliness and shivering. These merged into severe rigors and trembling. Her skin became ashen and her lips and nail beds cyanotic. The blood pressure was 100/80 and fell to 90/60 at the end of the chill. The pulse was rapid, full and bounding. The chills lasted from thirty to fifty minutes and were followed by a temperature, pulse rate and respiratory rate of 104.6 F., 120 and 24, which levels were maintained for from four to five hours, falling gradually to 99.2 F., 100 and 26 at the end of twelve hours. *Plasmodium vivax* was identified in the blood stream on the third day after the first chill.

At the height of the third chill, the following laboratory observations were noted: icteric index 18, blood sugar 79 mg. per hundred cubic centimeters, serum protein 5.7 Gm., urea nitrogen 15 mg., serum chlorides 98 milliequivalents per liter, serum carbon dioxide 57 volumes per cent, reticulocytes 4.2 per cent, red blood cells 3,660,000, whole blood inorganic phosphorus 3.4 mg. per hundred cubic centimeters and serum cholesterol 92 mg.

The paroxysms of chills and fever occurred daily, and the patient became listless and apathetic. She lost her appetite, perspired profusely during the defervescence of fever and was occasionally incontinent of urine. On the day of the sixth chill the patient was weak, her skin was pale and icteric and she complained bitterly of the increasingly severe rigors. The pulse was rapid and of small volume. The liver extended 4 cm. below the costal margin and the lymph glands were soft, nontender and discrete and enlarged to the size of beans. Red blood cells numbered 3,220,000, hemoglobin content was 65 per cent, white blood cells numbered 17,150: neutrophils 44 per cent, lymphocytes 32 per cent, monocytes 4 per cent. The icteric index was 18. Urinalysis gave negative results. She was given quinine sulfate, 15 grains (1 Gm.) every four hours for three doses, then 10 grains (0.65 Gm.) daily for sixteen days, together with reduced iron 10 grains three times a day. The chills stopped immediately. The parasites disappeared from the blood stream within three days, the liver edge receded to the rib margin and the lymph glands became smaller and firm. She no longer complained of the extreme feeling of weakness and helplessness present during the course of the chills. After six days of antimalaria therapy, the red blood cells dropped to 2,450,000 and the white blood cells rose to 18,150; neutrophils 38 per cent, lymphocytes 55 per cent, monocytes 4 per cent, eosinophils 2 per cent, and basophils 1 per cent. During the next eighteen days the blood picture rapidly changed to red cells 3,850,000, white cells 9,550, neutrophils 55 per cent, lymphocytes 41 per cent, monocytes 2 per cent, basophils 1 per cent, and reticulocytes 0.8 per cent. Serum cholesterol had risen to 138 mg. per hundred cubic centimeters, and blood sugar to 83 mg.; the urea nitrogen was 8 mg.

The patient gained weight and strength. Her emotional state was stable and cheerful and her responses were spontaneous. She could calculate with greater ease and accuracy, although her judgment remained somewhat impaired.

Injections of tryparsamide and bismuth salicylate were begun, and the patient was discharged one month after the onset of chills.

SUMMARY AND CONCLUSIONS

In general, with the exception of the occurrence of the early sustained fever, this patient reacted as does the usual patient with malaria. Interesting features in our case were:

1. Generalized lymphadenopathy, enlarged liver and absolute lymphocytosis during the course of paroxysms of chills and fever.
2. Failure of the blood sugar level to drop during a paroxysm.

3. A low blood cholesterol level during the paroxysms.
4. Prompt response of the malarial infection to quinine.
5. Atypical febrile episodes occurring before the onset of chills and the appearance of parasites in the blood stream.
6. A positive Weil-Felix reaction in high dilution.
7. The laboratory observations are presented without an attempt to interpret them.

This patient's course suggests that:

1. The absence of the spleen is no contraindication to the treatment of dementia paralytica with malaria.
2. It is probable that in cases of malaria in which the spleen is absent the lymphatic system compensates for whatever function that organ may have.

TRICHINOSIS: REPORT OF TRICHINAE IN VOCAL CORDS OF A PATIENT WITH DIPHTHERIA

ARCHIBALD L. HOYNE, M.D., AND A. A. WOLF, M.D., CHICAGO

From the literature it is evident that trichinosis occurs much more frequently than is generally supposed. It has been reported that on routine postmortem examination of several thousand diaphragms an incidence of trichinosis was found varying in different series from 13.6 per cent¹ to 17.5 per cent² and even as high as 28 per cent.³ Some believe the explanation for these figures lies in the fact that from 3 to 6 per cent of hogs are infected with trichinae.⁴

Trichinella spiralis belongs to the family of Nematelminthes or roundworms and enters the human body in raw or inadequately cooked pork. The gastric juices dissolve the protective capsule of the larvae and free the worm, allowing the latter to pass into the small intestine, where coitus occurs. The female then burrows under the surface of the intestinal mucosa and deposits viviparous young in the lymphatic and vascular structures.⁵ The larvae arrive at their destination in about nine days and encyst when they reach striped muscle. The capsule alone or the capsule and worm may then become calcified.⁶

Trichinae have been found in the spinal fluid,⁷ mesenteric lymph nodes, lungs, heart, pancreas,⁸ brain,⁹ gallbladder,¹⁰ placenta, milk of nursing mothers, pleural effusion and retina.

The symptoms produced follow the cycle of the worm:

1. Period of invasion of host or that period wherein the worms develop to maturity in the intestine. Gastrointestinal manifestations such as nausea, vomiting, diarrhea and abdominal pain occur at the end of the first week.
2. Period of dissemination of larvae or that period when the larvae are carried into the blood stream and lymphatics to become embedded in the striped muscle. There occurs then muscle tenderness, edema about the eyes and eosinophilia, this being at the end of the second week.
3. Period of encystment, which is the convalescent period in mild cases but in overwhelming infections marked edema of the face, severe cachexia, delirium and coma are produced.

From the Contagious Disease and Pediatric departments, Cook County Hospital.

The cardinal points in diagnosis are (1) history of eating raw pork, underdone pork or pork products, (2) gastrointestinal disturbances, (3) eosinophilia, (4) edema, usually suborbital, (5) high fever, (6) myositis and (7) myalgia.

The means of establishing the diagnosis are (1) biopsy, (2) examinations of the stool, blood and cerebrospinal fluid, (3) precipitation test and (4) the intradermal test. Of these, the Bachman intradermal test has proved of considerable value. It consists of a dried extract of the larvae diluted in a buffered saline solution. It is an intradermal test using 0.1 cc. of a 1:10,000 dilution and is read in from five to twenty minutes. A positive reaction raises a wheal of at least 7 mm. in diameter and a zone of erythema not less than 20 mm. in diameter. In about 90 per cent of persons a positive reaction develops in from two to four weeks after the onset of infection.¹¹

Trichinosis is uncommon in children because their gastric juices fail to dissolve the capsules of the larvae as occurs in adults. This explains why the larvae usually pass through the intestinal tract without causing infection and are excreted.

There have been recorded seventy-four cases of trichinosis in children, but we have found only three articles summarizing eleven cases in pediatric journals.¹² The clinical entity of

Development was normal, the baby having sat up at 5 months and walked at 10 months. There was no history of immunization or of contact with a patient with an infectious disease.

About five days before admission to the Cook County Hospital the mother noted that the child appeared to have a slight cold. Two days later there seemed to be fever, and on that account the mother decided to bring the patient to the hospital.

Examination.—On admission the infant was acutely ill. The rectal temperature was 103.6 F., the pulse rate 160 and the respiratory rate 60. The patient was listless and dyspneic and had a respiratory stridor.

A white membrane seemed to cover the mucous membranes of the nose. The pharynx was reddened and a white exudate concealed the left tonsil. A few submaxillary glands were palpable.

The boundaries of the heart were within normal limits with tones normal but rapid. Throughout the lung fields bilaterally were heard distinct breath sounds and coarse musical rales.

The abdomen and genitalia were normal and no pathologic neurologic reflexes were present.

Diagnostic Impressions and Possibilities.—The gradual onset of the disease, the age of the child (11 months), the history of no immunization and the presence of a membrane made possible a diagnosis of nasotonsillar laryngeal diphtheria. A streptococcal laryngotracheal bronchitis was also considered.

Clinical Course.—Intubation was done with a 1-2 year tube, which passed into the glottis with a sense of obstruction in the larynx. Because no relief was afforded, the tube was withdrawn and a 2-4 year tube inserted. Again no improvement was noted and a Mosher tube ("life saver") was introduced. However, the child was not benefited. Twenty thousand units of diphtheria antitoxin was administered intramuscularly. Epinephrine and caffeine with sodium benzoate were given and additional insertions of the Mosher tube were made, but the child's condition grew progressively worse and she died seven hours after entering the hospital.

Laboratory Studies.—Culture of material taken from the nose and throat for *Klebs-Loeffler bacillus* proved to be positive. Unfortunately no differential blood count was made.

The diagnosis made at necropsy was (1) pseudomembranous pharyngitis and laryngitis (diphtheritic), (2) trichinosis of the vocal cords, (3) parenchymatous degeneration of the myocardium and slight sclerosis of the endocardium of the left ventricle, (4) parenchymatous degeneration of the liver and kidneys, (5) focal bronchial pneumonia of the left lower pulmonary lobe and (6) moderate hyperplasia of the spleen.

Through the courtesy of the late Dr. Richard H. Jaffé, who performed the necropsy, we secured the accompanying photomicrograph. It shows a section of vocal cord in which trichinae are plainly visible.

COMMENT

We have reported this case for the following reasons: 1. As far as we know this is the first recorded instance of trichinae being found in the vocal cords. 2. Trichinosis occurs infrequently in children. 3. Diphtheria involving the larynx presented an unusual combination of conditions.

25 East Washington Street.

The Birth of Aesculapius.—It was above Epidaurus, on Mount Titthion, as we have seen, that Aesculapius was born, the son of the god Apollo and a maiden named Coronis. According to one legend, the young mother left her baby in the care of a shepherd and went off with a mortal man, at which Apollo was angry and gave the little boy to the centaur Cheiron to bring up and educate as a physician. Soon the child became so expert in healing human ills that he even brought the dead to life. This so maddened Zeus and Pluto that they conspired to kill Aesculapius. Again Apollo saved him, and when he was of age he married Epione, by whom he had several children, all doctors. Homer merely mentions the sons of Aesculapius as healing the battle wounds at Troy, but his daughters' names, Hygeia and Panacea, have become household words for the prevention of sickness.—Hurd-Mead, Kate Campbell: *A History of Women in Medicine*, Haddam, Conn., the Haddam Press, 1938.

Trichinae in vocal cord (courtesy of R. H. Jaffé); reduced from a photomicrograph with a magnification of 100 diameters.

trichinosis has been regarded lightly in didactic considerations at medical schools and is seldom considered in a differential diagnosis in hospital wards for children.

Twenty years ago one of us observed a child about 3 years of age who was sent to the Contagious Disease Department of the Cook County Hospital with a diagnosis of epidemic meningitis. We found trichinae in the spinal fluid, a rare disclosure at that time. (This case was not reported.) Since then there has been no recognized case of trichinosis occurring in a child among patients in our contagious disease department until the one responsible for the following report:

REPORT OF CASE

History.—M. C., an infant Negress, aged 11 months, was admitted to the Cook County Hospital July 4, 1937. The family and social histories were unsatisfactory. It was said that there were other children living and well.

The child was a full term normal infant weighing 9 pounds (4,082 Gm.) at birth. She was artificially fed on whole boiled milk formula and received cod liver oil and orange juice.

Special Article

THE HUMAN REQUIREMENT OF VITAMIN D

P. C. JEANS, M.D.

AND

GENEVIEVE STEARNS, PH.D.

IOWA CITY

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

For many persons some vitamin D in addition to that ordinarily obtained by exposure to sunshine is necessary for the most efficient utilization of calcium and phosphorus. The vitamin acts by increasing the amounts of these substances available for the mineralization of bones and teeth. Measurement of the requirement of vitamin D presupposes the ingestion of a diet adequate in all other respects and particularly containing ample amounts of calcium and phosphorus; it should include also recognition that the human requirement of vitamin D (or of any other nutritional factor) includes both the quantity necessary to prevent obvious clinical pathologic changes and an amount which promotes a condition of normal nutrition and health.

The requirements of vitamin D may be defined as those amounts which, with ample intakes of calcium and phosphorus and a diet otherwise adequate, insure sufficient retention of calcium and phosphorus to permit (a) normal growth and mineralization of the skeleton and teeth of infants and children, (b) maintenance of bony and dental structures during adult life and (c) a sufficient supply for mother and infant during pregnancy and lactation.

Unfortunately no one yet knows the normal rate of growth of children. Instead, there are available only many average rates of growth under widely varying conditions of nutrition. It is known from studies of racial food habits that when the diet of a people is nutritionally good and includes a plethora of milk and ingested vitamin D or its equivalent in sunlight the people of that race are tall and well formed, with well calcified skeletons and freedom from dental caries.¹ On the other hand, peoples whose mineral or vitamin D intake is very low are small of stature and prone to be subject to rickets or osteomalacia.² Even in this country, children from better class homes are taller and heavier than children of poor families,³ and children from better class homes of today are taller than those of the same class a generation or so ago.⁴ One may

postulate, therefore, that "average" rates of growth of today still represent suboptimal rather than optimal skeletal growth, so that, if linear growth is used as a criterion of adequacy of vitamin D intake, the rate should be at least "average."

During childhood and adolescence, not only does the skeleton grow in size but a part of its water content is replaced by inorganic salts. The rate of replacement is not known with certainty but is most rapid in early life. Because of the variability of standards of growth and mineralization of the skeleton, the optimal amounts of calcium and phosphorus to be retained at any age are not known. Various methods of calculating these requirements have appeared in the literature from time to time.⁵ The required retentions estimated for calcium by the different investigators vary from 0.1 Gm. daily throughout childhood^{5a} to a graded scale increasing from 0.3 Gm. daily at 1 year to 0.5 Gm. daily during adolescence.^{5c} As improvement in nutrition has so far resulted in increased average stature, and as mineralization of the skeleton may lag far behind growth,⁶ the higher figures are thought to be a safer guide.

The requirements of normal persons for only the ingested forms of vitamin D will be considered in the present discussion. The criteria commonly used are freedom from rickets or osteoporosis, good growth and development, normal values for serum calcium and phosphorus, ample retentions of these elements for growing individuals and "equilibrium" for those fully grown.

REQUIREMENT DURING INFANCY

Infants Fed Cow's Milk.—Studies of the vitamin D requirement during infancy may be divided into two groups. The larger group comprises studies planned to determine a minimal requirement using the prevention of rickets as the sole or chief criterion. Some of these include also the levels of serum calcium, phosphorus and phosphatase, and a few have taken into consideration the rates of growth. The smaller group comprises studies which include in addition to the preceding criteria quantitative determinations of the retention of calcium and phosphorus correlated with the rate of growth and the relative intakes of calcium and phosphorus. The emphasis in this group has been not on rickets prevention but on growth and development and on the fully adequate rather than the minimum requirement for vitamin D.

All these studies include periodic roentgen examination of the radius or tibia; in the first group of studies this constitutes the chief basis of judgment. Little agreement has been achieved in the interpretation of minor aberrations of growth at the epiphyseal line,⁷ but much greater uniformity in the determination of rickets of "clinical significance." Use of only the latter criterion is necessary if comparisons are to be made between the various studies. Rickets prevention alone probably should not be considered as a criterion of an adequate vitamin D supply. It is at least reasonable to think that the optimum amount of any nutri-

tional essential is somewhat greater than the amount which barely prevents clinical pathologic changes.

The determination of calcium and inorganic phosphorus of blood serum has a definite but limited usefulness in estimating the vitamin D requirement. In general, rickets cannot develop concurrently with a continuously normal level. The amounts of vitamin D that barely prevent rickets produce serum values within the range considered normal. However, values of this magnitude give little indication as to whether the calcium balance is weakly or strongly positive; it may even be negative. Perhaps one should distinguish between low and high normal levels. When the amount of vitamin D is considered fully adequate, the serum calcium and phosphorus levels then would be in the upper part of the normal range, whereas with amounts of vitamin D considered inadequate the serum values would be at the lower limits of normal.

The rate of growth is an important factor in determining the vitamin D requirement. Since rickets is a condition the severity of which tends to increase with increasing rates of growth, it is more important to prove that rickets has been prevented in a rapidly growing than in a slowly growing infant. Evidence is available also that the rate of growth is increased above the average when the intake of vitamin D is fully adequate.⁸

The most useful criterion of the vitamin D requirements is provided by studies of the utilization of calcium and phosphorus. Observations on the retention of these minerals permit a direct evaluation of the efficiency of utilization at different levels of vitamin D intake instead of the indirect estimates which have been discussed. This direct evaluation is the one procedure available which permits the estimation of an appropriate rather than a minimal requirement for vitamin D. Rickets prevention can be a criterion only in infancy, whereas the retained quantity of calcium and phosphorus offers a criterion for all age periods. Ample rather than minimal retention of calcium and phosphorus is required throughout the period of growth to supply material for new bone and for the replacement of water in bone already formed. Ample retention of these elements is desirable also to aid in compensating for the inevitable mineral losses in association with illness.

The consensus of various studies seems to be that the quantity of vitamin D received by a baby fed customary quantities of milk containing 135 units⁹ to the quart is sufficient to prevent the development of rickets in the majority of full term infants but insufficient to prevent moderate or severe rickets in prematurely born infants; that from 300 to 400 units daily as cod liver oil or as milk containing 400 units to the quart allows sufficient vitamin D to prevent rickets of clinical significance in both full term and prematurely born infants.¹⁰

Early studies reported different normal standards for the serum calcium and phosphorus levels of breast-fed and artificially fed babies. Later studies showed that artificially fed infants given adequate vitamin D had serum values equaling those of infants given human milk.¹¹ When infants are fed milk containing 135 units of vitamin D to the quart, the serum calcium and phosphorus values are normal, but higher dosages of vitamin D (from 300 to 400 units) permit levels nearer the top of the normal range.¹²

It has been observed that infants given milk containing 135 units to the quart tend to grow at average rates, whereas infants given from 300 to 400 units of vitamin D tend to grow somewhat faster than the average.^{8a} This observation has been corroborated recently.^{8b}

Studies of calcium and phosphorus retention¹³ have shown that infants given no additional vitamin D show marked variability in calcium retention with a low average. When from 60 to 135 units of vitamin D is given daily, the number of low retentions decreases, raising the average retention of the group. A further and significantly greater increase in average retention is obtained (by raising the lower limit of the retention range) when from 300 to 400 units of vitamin D is fed daily. Thus, increasing the vitamin D content of the diet from 0 to 300 or 400 units decreases variability of the infant in regard to ability to retain calcium and tends to raise all infants to the level of those most efficient in calcium retention. These studies show also that the calcium retentions observed when from 300 to 400 units of vitamin D is fed daily are accompanied by excellent dentition and the maintenance of serum calcium and phosphorus at high normal levels as well as by increased growth and development. The average retention observed when from 300 to 400 units of vitamin D is given apparently is ample to provide abundantly the nutritional needs for these minerals, even at the somewhat increased rate of skeletal growth observed.

Data are not available to show whether an amount of vitamin D between 135 and 300 units daily would be equally effective in permitting ample retention of calcium and phosphorus. Whatever the minimal level of vitamin D for good retention of these minerals, that level seems to be greater than 135 units.

A few observations indicate that amounts of vitamin D which are considerably in excess of 400 units daily may be detrimental when growth and retention are used as criteria. In an inpatient study, five infants given 1,500 or more units daily have shown decreased appetite accompanied by retardation of growth at or beyond 6 months of age. Decreasing the vitamin D intake of two of these infants has resulted in a greater food intake and an increased rate of growth.¹⁴ Further study will be necessary before the significance of these observations can be evaluated.

Present knowledge of the relationship of vitamin D to growth helps to explain the occasional diagnosis of

rickets by roentgenographic means when rickets probably is not present. The small changes used as criteria in the roentgenographic diagnosis of slight rickets occur when no vitamin D is given and tend ultimately to increase, producing the picture of clinical rickets. When from 60 to 135 units of vitamin D is given daily, a minimum number of these changes is reported in inpatient studies.^{7a} When from 300 to 400 units of vitamin D is given and growth is more rapid, a larger number of small changes in growth at the epiphysal line is reported, but these changes (in inpatient studies) never become any more definitely rachitic and accompany excellent retention of calcium with maintenance of serum calcium and phosphorus at high normal levels. From outpatient studies fewer bone changes are reported when large amounts of vitamin D are given. As the rate of growth seems to be nearly maximal with from 300 to 500 units of vitamin D,⁸ it seems that the small changes reported as evidence of early or very mild rickets may represent equally well changes due to rapidity of growth except when no vitamin D is given.

Factors other than those which have been discussed must be considered along with the vitamin D requirement. One of these is the relative ease of administration. This has been brought out in several published studies of outpatient groups in which it was found that the amount of rickets occurring was in direct proportion to the amount of cod liver oil prescribed.¹⁵ The apparent supremacy of vitamin D milks in outpatient studies may be ascribed to this cause.

Another factor requiring consideration is the relative efficacy of the different varieties of vitamin D. This question has been discussed at length in a previous review.^{1a} It is possible that vitamin D from vegetable sources (related to ergosterol) is less potent for man on a unit for unit basis than that from animal sources (related to cholesterol). The difference in potency between these two varieties, if any exists, is small, almost certainly no greater than 1:1.5, and probably less than this. Criteria capable of determining such a narrow difference must be most exacting, and a satisfactory answer to the problem does not seem possible with available information.

A factor of apparently greater importance than the source of vitamin D is its state of concentration or dispersion. It has long been believed on the basis of clinical experience that a greater unitage of vitamin D is required as viosterol in oil than as cod liver oil. It seems probable that a large part of this difference, if not all of it, may be explained on the basis of relative dispersion. Lewis,¹⁶ Erben¹⁷ and Shelling¹⁸ have shown in clinical experiments that irradiated ergosterol in a dispersed state is much more effective than the same material in a high concentration. The best concentration for efficient utilization is not known. Data^{12a} (from observations of infants receiving cod liver oil and various vitamin D milks) indicate that infants can utilize vitamin D in concentrations up to at least

100 units to the gram as efficiently as they utilize this vitamin in a highly dispersed state. The difference in utilization depending on concentration makes difficult the evaluation of data on the effect of higher dosages, for these high dosages have been given almost exclusively as concentrates or patent pharmaceutical preparations. The effect of the very high dosages in decreasing appetite suggests that a larger absolute amount is absorbed than with the smaller dosages of the dispersed forms; the disproportionate antirachitic effect between concentrated and dispersed forms indicates that a much smaller proportion is absorbed from the concentrates. In view of the strong probability that concentrated forms of vitamin D are not fully absorbed, it seems wise to proceed cautiously in administering to infants high unitages of the more dispersible forms of vitamin D. The actual limit of tolerance may be lower than the amounts which hitherto have been administered without toxic effect.

Tentatively the vitamin D requirement of the infant fed cow's milk may be stated as between 300 and 400 units daily, these amounts having been shown to be efficient in prophylaxis of rickets, in producing ample retention of calcium and phosphorus and in permitting excellent skeletal growth and dentition. This requirement is stated in terms of vitamin D of no greater concentration than is found in average high grade cod liver oil.

Infants Fed Human Milk.—The requirement of breast-fed infants for vitamin D is in general less than that of babies fed cow's milk. Infants fed human milk are less liable to the development of rickets when no vitamin D is given; however, rickets is by no means rare. A study of the literature shows that the calcium retention of infants receiving human milk and no additional vitamin D is somewhat less variable than that of infants receiving cow's milk without vitamin D; but the number of low retention values observed is sufficient to account for the occasional development of rickets. In our laboratory four infants fed human milk were given from 300 to 400 units of vitamin D daily; the calcium retention was less variable than is reported for infants given no additional vitamin D, and the average retention was approximately 50 per cent higher. It seems that for infants fed human milk, as for artificially fed babies, the ingestion of vitamin D decreases the range of retention by increasing the efficiency of those with poor retentions to equal that of infants most efficient without vitamin D. It appears that for many breast-fed babies vitamin D is essential and for most of them it is useful. Though the requirement cannot be stated with accuracy on the basis of available data, it would seem wise to prescribe the same amount as is required by the artificially fed baby.

Prematurely Born Infants.—The vitamin D needs of prematurely born infants are not easy to determine because of the difficulty of supplying ample amounts of calcium and phosphorus during the first few weeks of extra-uterine life. Normally during the last month of full term pregnancy the fetal need of calcium is approximately 0.3 Gm. daily. Obviously it is not possible for a prematurely born infant fed human milk to ingest this quantity of calcium, much less to retain it. Even when the feedings are fortified with dried skimmed milk or calcium caseinate, the total calcium intake is usually under 0.6 Gm., an amount which may be considered scarcely sufficient to permit retention of 0.3 Gm. The prematurely born infant tends to grow

more rapidly than the infant born at term. The combination of increased growth and deficient intake is such a handicap that it is doubtful whether the ingestion of vitamin D can compensate entirely, though it may readily compensate to the extent of preventing rickets.

Davidson, Merritt and Chipman¹⁹ reported that irradiated evaporated milk is inadequate to protect prematurely born infants from moderate or severe rickets. The amount of vitamin D received by these babies varied from 24 to 59 units daily at the age of 1 month. These same authors^{19a} found that cow's milk containing 430 units of vitamin D to the quart protected against moderate and severe rickets but not against the roentgen signs of slight rickets. Reinterpretation of the data in the light of the preceding discussion of roentgenographic evidence of rickets in this review permits the exclusion of these cases of slight rickets and allows the conclusion that all the infants were protected. The amount of vitamin D received by these babies varied from 116 to 245 units with an average of 170 units at the age of 1 month. The average birth weight of the babies was 2,000 Gm., and the average weight at 1 month was 2,500 Gm. Horeh and Russell¹⁹ found complete protection against rickets in prematurely born infants from the use of a protein milk containing 3.8 cc. of cod liver oil to the quart. McQuarrie^{12b} obtained rickets prevention with 540 units daily as activated ergosterol. Davidson, Merritt and Chipman²⁰ reported that viosterol fed at a level of 3,150 units daily did not protect against roentgenographic evidence of slight rickets in prematurely born infants receiving human milk, cow's milk or mixed feeding, but again reinterpretation permits the conclusion that rickets was prevented. Shelling²¹ observed osteoporosis but not rickets in premature infants given from 3,500 to 4,500 units of vitamin D as viosterol. These reports indicate that rickets is prevented in prematurely born infants by an amount of vitamin D approximately twice that known to protect the majority of full term infants and that rickets is not prevented by an amount less than that required for full term infants. No means are at hand for comparing the relative effects of the same amount of vitamin D in the two groups. The possibility remains that the prematurely born baby requires no more vitamin D for the prevention of rickets than the baby born at term. For the full term infant the amount that permits ample retention of calcium is considerably greater than that which barely prevents rickets. No doubt this holds for the prematurely born baby also. Until further information is obtained it may be tentatively considered that prematurely born babies require twice as much vitamin D as babies born at term, or from 600 to 800 units fed in a dispersed form. After the period of most rapid growth in early infancy the requirement should be the same as for the full term infant.

REQUIREMENT DURING CHILDHOOD

The requirement for ingested vitamin D has been assumed to decline after infancy, though little experimental evidence for this supposition exists. Belief in this idea is reflected in the widespread lack of use of

vitamin D preparations in childhood compared to the almost universal use in infancy. The assumption of a lesser need may be based on the absence of rickets in childhood and on the presumption that older children get more sunshine than infants. Whether or not the fault is with vitamin D, there is abundant evidence that present customs of diet in this country are not fully adequate for optimal skeletal and dental development. This is attested by the prevalence of dental caries and, in late childhood, the finding of osteoporosis. As a cause of these abnormalities a deficiency of intake of calcium, vitamin D or both substances is probably more common with the American type of diet than an intake deficient in phosphorus. At least some of these defects may be caused by inadequacy of vitamin D.

The criteria of adequacy of intake of vitamin D are fewer for children than for infants. Prevention of rickets is of no value and studies of levels of calcium and phosphorus in the blood are of little assistance. The rate of growth might be useful, but no studies have come to our attention in which this criterion was used when vitamin D was the only factor varied. A criterion which has a considerable degree of usefulness is the prevention and arrest of dental caries. The most satisfactory criterion subject to quantitative measurement is the retention of calcium and phosphorus with and without vitamin D, compared with the calculated requirement for these minerals.

Dental Caries.—Numerous observations have shown that vitamin D is a factor in prevention and arrest of dental caries. In some instances vitamin D has been added to the diet in an orphanage or other group without other change. The effect on the teeth has been variable, as is to be expected. It is worth reiterating that vitamin D does not reduce the minimum requirement for calcium and that vitamin D may not be expected to improve a diet containing an amount of calcium below the minimum requirement. In order to determine the vitamin D requirement by using the criterion of dental caries, the diet must be adequate in all respects other than vitamin D, including adequate calcium and phosphorus.

Mellanby²² administered cod liver oil in an amount containing from 700 to 1,500 units of vitamin D daily as a supplement in orphanage diets which happened to be deficient in fruits and animal protein and which contained about 500 cc. of milk daily. Mellanby reported that the children to whom cod liver oil had been given developed fewer new cavities and showed arrested progress of old caries, although carious activity was not entirely prevented. A somewhat similar type of observation by Day and Sedwick²³ gave negative results. They found no change in the carious processes in a group of school children for whom was prescribed 4,000 units of vitamin D daily as viosterol, as compared to a control group not receiving vitamin D. These children lived at home and the diets were uncontrolled. Anderson and his co-workers²⁴ noted a "marked decrease" in dental caries when viosterol (4,700 units) was administered to children with presumably good diets. McBeath²⁵ reported reduced

incidence of dental caries in an orphanage group whose diets are recorded as "good," when 10,000 units of vitamin D as viosterol was given daily without other dietary change. It is evident from the observations cited and others in the literature that vitamin D is a factor in the arrest and control of dental caries, but most of these reports give no clue to the vitamin D requirement.

McBeath²⁶ has reported the prevention of dental caries with the administration of an excellent experimental diet including 3 teaspoonfuls of cod liver oil. He²⁶ has reported also in a winter study of orphanage children a decrease in the number of new carious processes when the unrecorded diet was altered by the addition of 1 pint of milk and by 1 pint of milk containing 270, 400 and 800 units of vitamin D respectively, the improvement in the dental condition being in the order stated. Decrease in caries produced by the addition of milk alone indicates that the basal diet may not have been adequate. The apparent superiority of 800 over 400 units of vitamin D may not be actual, because these unitages were employed in different orphanages and were not added to the same basal orphanage diet. However, definite superiority of 800 over 270 units was shown.

Boyd and Drain and their co-workers²⁷ observed rapid arrest of dental caries in children given a well rounded diet which included a quart of milk and about 350 units of vitamin D daily, the latter in the form of cod liver oil. In a recent intensive study of four children with dental decay these authors²⁸ noted the effect of diets otherwise adequate but with the vitamin D intakes graduated; 0, 155 and 600 units daily were given successively to the same children. The ingestion of a good diet without added vitamin D brought about appreciable lessening of the activity of the caries during the first few weeks of the study in the fall months with the children spending much time outdoors. Subsequently for a period of five months, during which the children received a diet of high protective value aside from its vitamin D content and through both the periods of no added vitamin D and of the 155 unit addition, the caries was stationary with minimal but definite activity. It was not until the higher amount of 600 units of vitamin D had been given for nine weeks that the caries became definitely arrested. The results with 600 units daily showed no advantage of this amount over the 350 units daily intake of previous experiments.

Incidentally it is worthy of mention that the studies of Boyd and Drain have pertained exclusively to dentinal caries, while most if not all other observers have included both caries of the dentin and of the enamel in their data. Included in the latter designation, lesions due to dystrophy, fracture and disintegration have been considered; any surface irregularities deep enough to catch the exploring tine have been designated as sites of decay. Obviously not all these bear relation to nutrition. This difference of interpretation must be evaluated in comparing studies of tooth decay. The effect of nutrition on enamel disintegration remains to be determined. It is possible that complete prevention of enamel "caries" by a nutritional regimen is not to be expected.

One may conclude from the dental studies that the greatest freedom from dental caries is observed in groups of children receiving an adequate diet containing ample quantities of milk and 350 or more units of vitamin D daily. If the diet is suboptimal, the addition of vitamin D lessens the severity but does not prevent dental caries. Similarly, a diet otherwise adequate but lacking in vitamin D may decrease the incidence but not prevent entirely the development of tooth decay, nor provide for complete arrest of caries already present.

Calcium and Phosphorus Retention.—Many studies of calcium and phosphorus retention of children are available, though in but few have comparative studies been made with and without vitamin D. Unlike studies throughout infancy, wherein the dietary regimen is known for the entire period after birth, observations in childhood are more likely to be handicapped by incomplete knowledge of the previous dietary regimen. Wang²⁹ has shown that if the child's previous diet has been deficient in calcium, the calcium retention during the period of observation may be unusually high. In our studies there have been observed also a few children whose previous diets had been deficient in calcium but who reacted very slowly to the change in diet; only after several weeks of ingestion of an adequate diet with added vitamin D did the calcium and phosphorus retention reach the average of the group. Because of the influence of previous dietary conditions on the retention observed from a given diet, it has become customary to allow a longer period of adjustment to the experimental diet than was formerly the custom and to make a series of retention studies rather than a single observation with each given dietary. When the experiment is conducted in this manner the results are more reliable.

The adequacy of a diet in calcium, phosphorus and vitamin D may be judged by comparing the retention observed with the quantities considered ample for osseous and dental development. Because the quantity of phosphorus retained varies with the nitrogen as well as the calcium retention, the quantity of calcium retention may be used as the most convenient guide. When the standards set up by Leitch³⁰ are recalculated into the more customary terms of retention per kilogram, the calcium retention considered desirable decreases from 25 mg. per kilogram for a year old child to from 10 to 12 mg. for a child over 6 years of age. These values are somewhat higher for young children than those postulated as desirable by Sherman and Hawley.³¹

Reports of long term studies of children not given vitamin D stress the variability of calcium retention observed in a group of children³⁰ or in the same child from period to period of study.³¹ The retention observed with an intake of 1 Gm. of calcium daily varied from 6 to 24 mg. per kilogram, and the average retention of some children was far below the amounts postulated as safe by Leitch.

Weld and Sykes³² determined the calcium and phosphorus retention of six children over a five week

period with an intake of 0.82 Gm. of calcium and no added vitamin D. During a second five week period 135 units of vitamin D as irradiated ergosterol was added to the diet of four of the children with no significant change observed in the retention.

We³³ studied fifty children aged from 1 to 12 years with varying intakes of milk and with and without added vitamin D. When given, the amount of vitamin D was from 300 to 400 units as cod liver oil daily. For the majority of these children each dietary regimen was maintained for from five to eight weeks. A few were studied for periods up to three months with one dietary regimen. All children were permitted outdoor exercise when weather allowed. The variability of retention noted by others when children were not given vitamin D was also observed in this series. The retention of the younger children was more variable than that of the older but less variable than had been observed in infants not given vitamin D. As with the infants, the addition of vitamin D decreased the variability of retention by decreasing the number of poor retentions. Thus, if a child utilized calcium efficiently without added vitamin D, the addition of the vitamin to the diet had little effect. If, however, the utilization was poor, the ingestion of vitamin D increased the retention of calcium. The increased retention was by no means always observed promptly; two of the children studied did not achieve retention equal to the average of their age group until the diet with vitamin D had been given for a period of from two to three months. One of these children had active dental caries at the beginning of the experiment; the caries remained active much longer than is customarily observed in this clinic. The retention observed in this group of fifty children indicates that the ingestion of vitamin D in no way decreases the quantity of calcium need but that it assures better utilization. A retention equal to that postulated by Leitch as desirable was consistently obtained when the milk intake was 750 cc. daily or higher and when vitamin D was given.

Daniels and her collaborators³⁴ fed vitamin D in daily amounts varying from approximately 1,200 units (15 cc. of cod liver oil) to 3,000 units or more (15 cc. of cod liver oil plus 8 drops of viosterol). Though these studies were of short duration, the study group was large. An average retention of about 10 mg. per kilogram was observed whether the intake of milk was 1 pint or 1 quart daily. These retention values are lower than those noted by Hunscher and her co-workers in long term studies of children of this age group not receiving additional vitamin D, and considerably lower than the average values observed by us in children of the same age range given from 300 to 400 units of vitamin D daily.

It seems from a summary of the studies which have been cited that the variability of response to the calcium of the diet is marked in young children not given vitamin D. Efficiency of utilization tends to increase with increasing age of the child, but even by 9 or 10 years of age many children seem unable to utilize efficiently the calcium and phosphorus of the diet unless vitamin D is also ingested. The daily allowance of at

least 750 cc. of milk together with from 300 to 400 units of vitamin D seems to permit consistently ample retention of calcium and phosphorus for proper development of bone and teeth. The data at hand are not sufficient to allow an accurate estimate of the optimal intake of vitamin D for children, though it appears probable that the total quantity needed daily is not greater than the amount required for infants, nor does it seem to be less.

ADOLESCENCE

The literature contains very few reports of studies of either the calcium or the vitamin D requirement of adolescents, notwithstanding the fact that this age period is of special importance because of the rapid skeletal growth. Leitch has estimated that a retention of from 500 to 700 mg. of calcium daily is necessary to maintain normal calcification during this period. The condition of the teeth of the average adolescent and the possible occurrence of osteoporosis³⁵ during this period of growth indicate inadequacy of present dietaries. Whether in this state of suboptimal calcification the need is primarily for calcium or for vitamin D is difficult to determine with the data at hand.

Herbst³⁵ in 1913 reported calcium retention of two boys aged 13 and 14 years, with a calcium intake of 0.62 and 0.64 Gm. daily. The younger, who was growing rapidly, retained 0.3 Gm. of calcium daily, the older 0.15 Gm. Wang and her associates³⁶ have summarized the scanty data in the older literature and have added twenty-three six day studies of girls from 12 to 15 years of age. Vitamin D was not given. In Wang's study the daily intake of calcium varied from 1.18 Gm. to 1.80 Gm. and the retention from 0.079 Gm. to 0.823 Gm., or from 1 to 19 mg. with an average of 11 mg. per kilogram; the average retention was 417 mg. daily, two thirds of the group retaining less than the Leitch standard of 500 mg. daily.

Henderson and Kelly³⁷ studied for twenty-four weeks the calcium retention of five African boys aged from 15 to 17 years. With the control diet containing 0.3 Gm. of calcium the boys lost calcium at a rate of approximately 0.1 Gm. a day. The addition of cod liver oil to the diet of one boy did not decrease the calcium loss. The diets of three of the subjects were then supplemented respectively with 1 pint of milk daily, a mineral mixture equivalent to the minerals of 1 pint of milk daily, and the mineral mixture with added cod liver oil. The calcium retention of each of the three boys was consistently positive, varying from 0.096 Gm. to 0.5 Gm. daily, the higher value being obtained with the addition of milk without cod liver oil. The data are insufficient to permit evaluation of the effect of vitamin D added to the increased diet but do demonstrate that the ingestion of vitamin D did not decrease the minimal requirement for calcium.

The data obtainable from studies of adolescents indicate that individuals are by no means equally efficient in retaining calcium without the ingestion of vitamin D. Apparently the variability in ability to utilize the calcium and phosphorus of the diet is a major factor in determining the quantity of these elements retained by adolescents as well as by younger

children. It is indicated also that vitamin D does not lower the minimum requirement for ingested calcium, though no estimate can be made as to the optimal intake of either calcium or vitamin D.

REQUIREMENTS OF ADULTS

Men and Nonpregnant Women.—During adult life the quantity of calcium and phosphorus considered necessary is only that amount sufficient for maintenance. It may be found that some retention of calcium and phosphorus is desirable, at least during the post-adolescent period. Whether the addition of vitamin D may be necessary to insure such retention or whether the ingestion of vitamin D would insure better utilization of an intake only slightly above minimal requirements are questions difficult to answer with the few data at hand.

Much of the calcium intake of adults may be from sources other than milk; therefore the acid-base ratio of the diet assumes importance. The ingestion of an acid-ash diet or of acid salts increases the urinary excretion of calcium. If the intake is low, the added excretion may be sufficient to cause a negative calcium balance. Wide differences in intake ratios of calcium and phosphorus apparently have less effect on the retention of these elements by adults³⁸ than by children.³⁹

Leitch^{5c} has summarized the data for the calcium requirement of women not ingesting vitamin D. She concluded that, at or above a daily intake of 0.55 Gm. of calcium, losses of one period were equaled by gains of another, whereas below this intake output usually exceeded intake. The minimum calcium requirement as set by Sherman⁴⁰ is somewhat lower; namely, 0.45 Gm. a day. Few data are available concerning the requirement for men, but such as there are^{5c} indicate that the daily requirement is about the same as for women.

Most of the published studies of the effect of vitamin D on calcium and phosphorus retention of adults have centered on an attempt to determine whether an increased ingestion of vitamin D decreases the minimal requirement for calcium. The answer is unanimously in the negative.⁴¹ When vitamin D has been given as an addition to a diet containing more than the minimal requirement of calcium, the results have been conflicting. All the subjects studied by Kelly and Henderson⁴¹ and by Bauer and his co-workers⁴¹ retained calcium when the intake of this element was ample and no vitamin D was ingested. A further increase in retention was noted by Kelly and Henderson when cod liver oil was given in addition to the increased mineral intake. Bauer and his collaborators observed no increase in retention when from 30 to 90 mg. of irradiated ergosterol was given in addition to the high calcium diet but did obtain evidence of increased absorption, for the urinary excretion of calcium was increased and the fecal calcium correspondingly decreased when vitamin D was given. Hunscher and

her co-workers⁴² studied three young women whose calcium intake varied from 0.7 to 1.0 Gm. a day, amounts ordinarily considered ample. When no vitamin D was given two of the three women consistently lost 0.1 Gm. of calcium a day, the third was approximately in calcium equilibrium. When 15 Gm. of cod liver oil was given daily for twenty-three days the average calcium losses were not decreased, nor do the data show any significant alteration in the mode of calcium excretion.

Data are not available as to the effect of vitamin D on retention of calcium and phosphorus by middle-aged or elderly persons. The prevalence of senile osteoporosis may be due wholly to the habit common to most American adults of ingesting diets low in calcium. It has been shown⁴³ that mineralization of bone can be increased in adults past 60 by increasing the intake of calcium and vitamin D. Since elderly persons are less likely to be exposed to sunlight than more vigorous younger adults, the ingestion of moderate amounts of vitamin D, together with a diet ample in calcium and phosphorus, might serve to prevent the development of osteoporosis in the older adult.

Animal studies bearing on these questions include those of Sherman and Campbell,⁶⁰ who showed that when young rats are given a diet somewhat subminimal in calcium content, normal growth occurs, but normal calcification of bone is not achieved until nearly middle age. A recent report of these authors⁴⁴ lists an ample intake of calcium among the factors resulting in longer life and extension of the period of adult vitality of rats. Even if these observations are assumed to hold for human beings, there still remains to be determined whether and how much vitamin D would contribute to better utilization of calcium by adults.

The observations on adults indicate, as for children, that the ingestion of vitamin D in no way lessens the requirement for calcium. Whether vitamin D, when given in addition to an ample mineral intake, increases the utilization of calcium undoubtedly varies with the person. Although the average adult seems more efficient in the absorption of calcium than the average child, vitamin D may aid the inefficient adult in the same manner as the inefficient child. If this is true, the amount of vitamin D optimal for this purpose remains to be determined.

Reed and others⁴⁵ have given vitamin D in enormous dosage to adults, with apparently few untoward effects. The limit of tolerance varies with the individual but seems to be 150,000 units or more. The vitamin in these studies was given always as a very concentrated product. Whether adults utilize the concentrated sources of vitamin D efficiently or not, the enormous unitage given can be interpreted as indicating that the tolerance of the adult to vitamin D must be relatively high.

Pregnancy and Lactation.—The calcium and phosphorus requirement during pregnancy and lactation has

received much intensive study. The report of Bauer and Aub⁴⁶ indicates that with a subminimal intake the pregnant woman is unable to conserve calcium for the needs of the fetus. The Toveruds⁴⁷ observed that when the mother's diet was deficient, the skull of the infant was softer than normal, the epiphyseal lines, particularly of the metacarpals, were fringed and poorly calcified, and the teeth when erupted were often grossly hypoplastic. They observed further that when the mother's diet contained ample calcium and vitamin D, the bones and teeth of the infant were normal. Finola⁴⁸ and his co-workers noted a significant increase in the density of bone and a decrease in the size of the fontanel of babies whose mothers received a good diet plus approximately 1.5 Gm. of calcium as dicalcium phosphate and 7,000 units of vitamin D as viosterol, in comparison with infants whose mothers received a good diet without the addition of calcium and vitamin D.

The Toveruds⁴⁷ and Mellanby⁴⁹ both consider a poor diet of the mother during pregnancy as one of the chief predisposing factors in the development of rickets and dental caries in the children. Calcium and vitamin D are two of the factors most often deficient in the mother's diet. Corroborative evidence of the need of increased mineral retention in pregnancy is obtained in the study of Drain and Oberst⁵⁰ wherein the dental condition of pregnant women was shown to be improved by a diet rich in calcium and vitamin D.

The work of many investigators⁵¹ demonstrates that a calcium intake of at least 1.4 to 1.6 Gm. daily is necessary in order to permit retention of the amount of calcium needed by the fetus. Below this intake the addition of vitamin D does not insure retention. With a calcium intake of from 1.6 to 2.5 Gm. some persons can retain calcium in ample amounts even without added vitamin D. Studies of multiparas⁵² show that the drain of rapidly succeeding pregnancies and periods of lactation may result in poor retention of calcium and phosphorus regardless of intake unless vitamin D is also given. Very few show poor retention with a high intake of calcium even when the vitamin D intake is equivalent to 20 Gm. of cod liver oil. In general the addition of vitamin D in amounts supplied by from 10 to 20 Gm. of cod liver oil daily tends to increase

the retention of calcium and phosphorus. Insufficient studies have been made with ample intake of calcium and varying amounts of vitamin D to permit a conclusion or general statement as to the vitamin D requirement during pregnancy.

The studies of lactation⁵³ indicate that the drain on the mother is more severe than in pregnancy. The need for ample calcium intake is imperative. There seems necessary an intake of at least 1½ quarts of milk, containing 1.8 Gm. of calcium and representing a total day's intake of more than 2 Gm. Even then, relatively few women are efficient enough to prevent loss of calcium from the body unless additional vitamin D is given. Desirable amounts of vitamin D seem to vary with the individual, as shown by the following unpublished study from our laboratory: Two primiparas, aged 21 and 26, ingested good diets, each containing 1,500 cc. of milk and one teaspoonful of cod liver oil (from 350 to 400 units) daily. The 21 year old woman secreted from 1,000 to 1,500 cc. of milk daily and retained calcium continuously. The other woman secreted never more than 600 cc. of milk a day yet continuously lost calcium from the body; increasing the calcium intake decreased the loss but did not prevent it entirely. Again, two other primiparas, aged 17 and 19, were given from 1,800 to 2,000 cc. of milk daily. One retained calcium consistently throughout lactation; the other was unable to retain calcium until from 750 to 800 units of vitamin D daily as cod liver oil was given. The milk output of the latter was approximately 1,500 cc. and that of the former approximately 1,000 cc. a day.

Hunscher's studies⁵⁴ tend to show that in rapidly succeeding pregnancies and lactation periods vitamin D is especially necessary and that ample calcium intake does not suffice to prevent loss of calcium from the body unless vitamin D is given.

One factor often overlooked is the effect of the maternal diet on the quality of the milk secreted. Telfer⁵⁴ commented on the higher mineral content of milk of country women compared to that of women from cities. The differences were ascribed to diet and to the relative amount of sunlight. The Toveruds⁴⁷ found a low calcium content in the milk of fourteen mothers whose diets were poor; when the calcium intake was increased the calcium content of the milk of each woman was increased after one week, the average increase being about 25 per cent. The effect of added vitamin D was not studied, but the possibility of its ingestion increasing the calcium content of the milk should not be ignored. The content of calcium in human milk varies considerably according to reports.

While available data point strongly to the advisability of giving vitamin D during pregnancy and lactation, it is impossible with our present information to arrive at any conclusion regarding optimal dosage. Individual variability has been demonstrated. The amount of vitamin D to be recommended is that which is desirable for the least efficient in utilizing the calcium of the diet. This amount may be greater, especially during lactation, than at any other period of life.

Animal experiments wherein large amounts of vitamin D were given to pregnant rats show that, if the maternal diet is good, the calcium and phosphorus content of the bones of the young rats is increased above that of the control group;⁵⁵ large doses of viosterol together with a deficient diet result in decreased content of mineral in the bones of young.⁵⁶ Subtoxic doses of vitamin D given to rats receiving a diet deficient in minerals during gestation increase the calcium and phosphorus content of the offspring over that of young born of mothers given the deficient diet without added vitamin D.⁵⁶ Hypervitaminosis D has not been reported in women during pregnancy and lactation; consequently the effect is unknown.

SUMMARY

Individual variation in ability to utilize the calcium and phosphorus of the diet without added vitamin D exists at all age periods. A high proportion of infants have poor retention and only a very few retain an ample amount without vitamin D. As the age increases persons in increased proportion are able to retain adequate amounts of these minerals without vitamin D, but at all age periods some persons are found who are not efficient. In defining a standard for the vitamin D requirement it seems desirable to state an amount which will be satisfactory for those who are less efficient. Vitamin D tends to decrease the range of retention of calcium and phosphorus in study groups by increasing the retention of those least efficient to approximate that of those most efficient. Vitamin D ordinarily does not increase the retention of those who have high retention without it.

Vitamin D does not decrease the minimum requirement of calcium and phosphorus and this vitamin cannot produce a good retention in a person who is ingesting less than the requirement for these minerals. Determination of the need for vitamin D must be based on studies of persons who are receiving an ample intake of calcium and phosphorus.

It appears from available evidence that vitamin D is not as well utilized on a unit for unit basis from the more concentrated preparations as from those preparations in which it is more widely dispersed. The most desirable concentration has not been determined, but apparently the concentration found in cod liver oil is as effective as any lesser concentration studied.

On the basis of the preceding premises and of an evaluation of data in the literature the requirement for vitamin D for different age periods and conditions has been tentatively postulated. These requirements are considered in terms of a concentration of vitamin D no greater than is found in average high grade cod liver oil.

The vitamin D requirement of the full term artificially fed baby is probably between 300 and 400 units a day.

Normal babies receiving human milk require less vitamin D than do babies receiving cow's milk, but how much less is not known. However, vitamin D is necessary for many and useful for most breast-fed babies. It would seem wise to prescribe for them the same amount as is required by artificially fed babies.

It is tentatively considered that prematurely born babies may require twice as much vitamin D as full term babies during the early period of most rapid

growth, after which time the requirement should be the same as for babies born at term.

For children between infancy and adolescence a daily allowance of at least 750 cc. of milk together with from 300 to 400 units of vitamin D permits consistently ample retention of calcium and phosphorus. The optimal quantity of vitamin D cannot be stated accurately, though it appears probable that the total quantity needed is neither greater nor less than the amount required for the infant.

For adolescents a need for vitamin D exists, but insufficient data are available to permit an estimate of the quantity required. It seems probable that from 300 to 400 units a day would be satisfactory.

For adults the optimal amount of vitamin D, if a need exists, remains to be determined.

It appears strongly advisable to give vitamin D during pregnancy and lactation. The optimal amount is not known. During lactation the requirement may be greater than at any other period of life and a daily dosage of 800 units or more is suggested, together with an abundant intake of calcium and phosphorus.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

ELECTROSTATIC AIR CLEANER ACCEPTABLE

Manufacturer: Westinghouse Electric Manufacturing Company.

Distributor: Atmospheric Electric Filter Corporation, Woolworth Building, New York.

The Electrostatic Air Cleaner is designed, according to the manufacturer, to remove smoke, dust, pollens and other impurities from outside or inside air by an electrostatic filter system. The portable unit comes in a walnut or ivory cabinet, 34 inches long by 34 inches high by 18 inches deep, weighing approximately 150 pounds. It may be installed in a window. Connection for the fresh air supply is made by a sliding window-block arrangement. The firm states that the unit will also aid in eliminating drafts and street noises.

The filter operates, it is said, by ionizing the dust particles in a chamber containing three high tension wires. Negative charges are imparted to the dust particles. Then, as they move on and pass through the collector plates bearing positive charges, the ionized particles are drawn toward the plates and stick to them. The air is drawn through the cleaning unit by means of a fan which is not noisy in operation. The cleaner does not remove all gases

Electrostatic Air Cleaner.

and vapors, since some particles are too minute to be deposited in the foregoing manner. The integral part containing the collector plates where the dust and pollen lodge may be removed and a hose turned on it for cleaning purposes.

An investigator acceptable to the Council tested the unit for efficiency in removing pollen from the air. The tests were made during the hay fever season of 1937.

Slides coated with petrolatum were exposed at the outlet of the unit and were examined for pollen granules. Slides were also exposed outdoors to obtain the pollen count for the same period of time by the method described by O. C. Durham. On only one or two occasions were any pollen granules observed on the slides exposed at the outlet ducts; never more than two per unit area of 1 square centimeter in a twenty-

55. Nicholas, H. D., and Kuhn, Evelyn M.: Role of Calcium, Phosphorus and Vitamin D in Pregnancy, *J. Clin. Investigation* 11:1313 (Nov.) 1932.

56. Sentag, L. W.; Munson, Paul, and Huff, Elton: Effects on Fetus of Hypervitaminosis D and Calcium and Phosphorus Deficiency During Pregnancy, *Am. J. Dis. Child.* 51:302 (Feb.) 1936.

four hour period, while the pollen count outdoors during this period averaged from 100 to 400 granules per square centimeter.

The unit was put out of service August 29 and was again started on the night of September 6, with a fresh batch of slides at the outlet duct prior to operation. These slides were again changed within one hour and showed several pollen granules and dust particles ranging as high as from 12 to 15 microns in diameter. However, slides placed in position at the outlet duct as the first batch were removed did not show any pollen and very little dust within the succeeding twenty-four hours. The pollen count at this particular time, however, was quite low. One would assume from these results that, during the time the Electrostatic Air Cleaner was turned off, pollen and dust which had adhered to the plates had dropped to the bottom of the cell and with the first blast of air had been blown through.

The unit was tested for its air volume by the anemometer method. The average of a group of readings with the damper opened gave 211 cubic feet per minute or 12,860 cubic feet per hour. With the damper shut, that is, with the recirculation in effect, the readings were 214 cubic feet per minute or 12,900 cubic feet per hour. The investigator's conclusion was that this filter is efficient for removal of a large portion of pollen and dust particles from the air.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Electrostatic Air Cleaner for inclusion in its list of accepted devices.

SPENCER MATERNITY SUPPORTS ACCEPTABLE

Manufacturer: Spencer Corset Company, Inc., New Haven, Conn.

The Spencer Maternity Supports are designed to aid in upholding the back and abdomen during pregnancy and are adaptable for increases in size of figure. The firm claims that the garment is built to place the weight of support on the pelvic girdle, thus relieving lumbosacral strain. Each support is made according to individual measurements submitted by the corsétière, the saleswoman for the company. Light weight flexible material is incorporated in the finished product, which may be laundered. The boning in Spencer supports is of special steel covered with a material claimed to be impervious to moisture. This boning is called Spencerbone, because it is manufactured exclusively for the firm and from its own formula.

The abdomen is supported by a nonelastic adjustable inner section, which is joined to the nonelastic backing by three straps on either side. The backing is made high and long enough for the individual figure. Abdominal uplift is regulated by adjustment of the lower straps. Because special elastic lacers are used, the only daily adjustment necessary is that of the inner supporting section.

The supporting section and straps are covered by the front part of the corset, thus presenting a smooth surface for the outer clothing to fit over. The section of the material to which eyelets are attached for lacers is placed so that the imprint of the lacers will not be insinuated onto the outer clothing. One elastic lacer extends the full length of the garment in front; there is another lacer at each side front extending from the top to the groin line. These are adjusted only as increasing size demands. Hooks and eyes are used for fastening the garment.

According to the Spencer Corset Company, these supports are sold through their sales representatives (women), known as Spencer corsétières. The corsétières are not permitted to diagnose; they are required to cooperate with the physician by fitting the type of support he prescribes. They are also instructed to arrange for the physician's inspection of a completed and fitted garment, whenever it is possible. All garments are designed for the individual patient. The company claims that no stock garments are made or sold.

The Spencer Corset Company has informed the Council that it has never paid commissions or rebated any percentage of the selling price to physicians on any of its merchandise, and assures the Council that it will not do so in the future. Furthermore, the manufacturer has stated that the corsétières

are under instructions not to pay commissions or gratuities of any kind and that any violation of this rule would cause them to lose their franchises.

These garments have been investigated by reliable physicians, who state that they render satisfactory service to obstetric patients.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Spencer Maternity Support for inclusion in its list of accepted devices.

BURDICK SWD-50 SHORT WAVE DIATHERMY ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The Burdick SWD-50 portable short wave diathermy unit is designed for medical diathermy and for minor electrosurgery. Standard accessories are available for cutting and coagulating purposes. The unit is made of furniture steel with all metal welded construction. The portable unit weighs approximately 60 pounds, while the lower cabinet weighs 35 pounds.

A two-tube push-pull self-rectified circuit is utilized with loose inductive coupling to patient's electrodes. The wavelength is 15 meters. The patient's circuit is turned by a wide range variable resonance control. Two patient's outlets are provided, one for use with large pads and average spacing, one for small pads with thicker spacing.

The firm claims that the unit has an output of 325 watts as measured by a lamp load, photoelectric cell and wattmeter. The input is approximately 720 watts. These claims were confirmed by an investigator acceptable to the Council. Transformer temperature rise and the rise at various levels within the cabinet after a two hour run at full load were within the limits of safety. Radio interference is minimized by the type of construction and inclusion of an inductance capacity filter in the line supply.

Schematic diagram of circuit.

Six tests, performed by a reliable investigator, were submitted as evidence of the ability of the SWD-50 unit to produce heat deep in human tissues. The technical procedure for making the tests was that recommended by the Council on Physical Therapy. Six observations were made with the cuff technic. These were

23½ by 2½ inches in dimension. The average distance of the cuffs, center to center, was 8½ inches. Felt and four thicknesses of a hand towel were used to secure a necessary five-eighths inch skin electrode distance. Skin tolerance was not exceeded. The averages for the six tests are as follows:

Average of Six Observations, Cuff Technic			
Deep Muscle		Oral	
Initial	Final	Initial	Final
98.0	106.1	98.6	99.0

The unit was tested clinically by a reliable investigator and he reported that it produced satisfactory clinical results in a large and mixed group selected for study when the cuff technic is used.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Burdick SWD-50 Short Wave Diathermy Unit for inclusion in its list of accepted devices.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

(1) NUTRADIET YELLOW CLING PEACHES PACKED IN WATER

(2) NUTRADIET SLICED YELLOW CLING PEACHES PACKED IN WATER

Distributor.—The Nutradiet Company, a subsidiary of S & W Fine Foods, Inc., San Francisco.

Description.—Canned, peeled, halved and sliced Yellow Cling peaches packed in water without added sugar.

Manufacture.—Tree-ripened Yellow Cling peaches, from trees on which no insecticide spray is used after the blossoms appear, are mechanically cut in halves and the pits are removed. The fruit is immersed in a 2 per cent solution of caustic soda to remove the skins, thoroughly washed, inspected, graded [(2) sliced] and packed in cans. Water is added and the containers are exhausted in the presence of steam, sealed and processed in boiling water.

Analyses (submitted by manufacturer).—(1) Moisture 92.8%, total solids 7.2%, ash 0.2%, fat (ether extract) 0.1%, protein ($N \times 6.25$) 0.4%, crude fiber 0.25%, carbohydrates other than crude fiber (by difference) 5.85%, titratable acidity as citric acid and/or malic acid 0.4%. (2) Moisture 93.1%, total solids 6.9%, ash 0.2%, fat (ether extract) 0.1%, protein ($N \times 6.25$) 0.3%, crude fiber 0.23%, carbohydrates other than crude fiber (by difference) 5.8%, titratable acidity as citric acid and/or malic acid 0.3%.

Calories.—(1) 0.26 per gram; 7 per ounce.

(2) 0.25 per gram; 7 per ounce.

Claims of Manufacturer.—For diets in which sweetened fruit is proscribed.

SUNFILLED BRAND CONCENTRATED ORANGE JUICE

Manufacturer.—Citrus Concentrates, Inc., Dunedin, Fla.

Description.—Canned concentrated orange juice prepared from Florida oranges.

Manufacture.—Tree-ripened sound oranges are inspected, washed and mechanically split. The juice is extracted by gentle pressure, strained, evaporated to about one tenth its original volume, automatically filled into cans and sealed under reduced pressure.

Analysis (submitted by manufacturer).—Moisture 24.0%, total solids 76.0%, ash 2.7%, protein ($N \times 6.25$) 3.5%, reducing sugar as invert 26.0%, sucrose 31.3%, carbohydrates (by difference) 63.3%, citric acid 6.5%, vitamin C (iodine titration) 2.5 mg. per gram, specific gravity 1.369.

Calories.—2.67 per gram; 76 per ounce.

Vitamins.—The concentrate, when diluted with 9 parts of water by volume, furnishes approximately 645 international units of vitamin C per hundred grams of solution.

MULL-SOY

Manufacturer.—The Muller Laboratories, Baltimore.

Description.—A food preparation for use as a substitute for milk in feeding infants, older children or adults who are sensitive to the proteins of cow's milk. Contains soy bean flour, soy bean oil, dextrose, sucrose, calcium phosphate, sodium chloride, calcium carbonate and cod liver oil concentrate.

Manufacture.—The soy bean flour ingredient is prepared by the "expeller" process, in which soy beans are heated under steam pressure, split and hulled, and again heated. The oil is pressed out and the resulting cake is ground to flour. Formula proportions of the solid ingredients are thoroughly mixed

with suitable amounts of water and heated; soy bean oil and cod liver oil concentrate are added and the mixture is homogenized, heated, and filled into cans. The sealed cans are heat processed.

Analysis (submitted by manufacturer).—Moisture 75.0%, total solids 25.0%, ash 2.0%, fat (ether extract) 7.8%, protein ($N \times 6.25$) 6.0%, crude fiber 0.3%, sucrose 1.5%, dextrose 3.3%, total carbohydrates other than crude fiber (by difference) 8.9%, calcium (Ca) 0.26%, phosphorus (P) 0.22%, sodium (Na) 0.16%.

Calories.—1.3 per gram; 37 per avoirdupois ounce; 40 per fluidounce.

Vitamins.—Vitamin A, 4.4 international units per gram; 2,000 international units per quart when diluted with an equal volume of water. Vitamin B₁, 0.2 international unit per gram; approximately 100 international units per diluted quart. Vitamin D, 0.9 international unit per gram; approximately 400 international units per diluted quart.

MRS. PALEY'S BABY FOOD--STRAINED EVAPORATED PEACHES

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

Description.—Cooked, sieved, sulfured dried peaches, packed with added dextrose.

Manufacture.—Dried, sulfured peaches are washed, soaked for twelve hours, precooked in pressure cookers with added dextrose, sieved, filled into glass jars, vacuum sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 73.5%, total solids 26.5%, ash 1.0%, fat (ether extract) 0.3%, protein ($N \times 6.25$) 1.6%, reducing sugars as dextrose 11.9%, sucrose 7.3%, crude fiber 0.5%, total carbohydrates other than crude fiber (by difference) 23.1%, calcium (Ca) 0.022%, phosphorus (P) 0.043%, iron (Fe) 0.003%, sulfur dioxide (SO₂) 0.0156%.

Calories.—1 per gram; 28.4 per ounce.

HEKMAN'S 100 PER CENT WHOLE WHEAT RUSK

Manufacturer.—Dutch Tea Rusk Company, Holland, Mich.

Description.—Round slices of toast prepared from whole wheat flour, milk, brown sugar, eggs, vegetable shortening, yeast, malt extract, salt and soda.

Manufacture.—A dough is made of the foregoing ingredients and allowed to ferment. The pieces of dough (buns) are baked in round covered pans, sliced and the halves dried, toasted and packed in cartons.

Analysis (submitted by manufacturer).—Moisture 8.6%, total solids 91.4%, ash 1.8%, fat (ether extract) 8.9%, protein ($N \times 6.25$) 13.6%, crude fiber 1.9%, total carbohydrates other than crude fiber (by difference) 65.2%, iron 0.0057%.

Calories.—3.95 per gram; 112 per ounce; about 60 per rusk.

MRS. PALEY'S BABY FOOD-- STRAINED TOMATOES

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

Description.—Canned, sieved tomatoes, slightly seasoned with salt.

Manufacture.—Fresh tomatoes are thoroughly washed, trimmed, cooked until soft and sieved. The sieved tomatoes are reduced to the desired consistency by cooking in the absence of air, filled into glass jars, vacuum sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 93.5%, total solids 6.5%, ash 0.1%, fat (ether extract) 0.1%, protein ($N \times 6.25$) 1.1%, reducing sugars as dextrose 2.8%, sucrose 0.6%, crude fiber 0.3%, total carbohydrates other than crude fiber (by difference) 4.9%, calcium (Ca) 0.0184%, phosphorus (P) 0.015%, iron (Fe) 0.0018%.

Calories.—0.2 per gram; 6 per ounce.

THE NEED OF SPECIAL TRAINING IN THE DIAGNOSIS AND TREATMENT OF CANCER

The recent movement for the organization of cancer clinics is based on the principle that the best results can be obtained in the diagnosis and treatment of the cancerous diseases by formally organized and close cooperation between the pathologist, the surgeon and the radiotherapist. The personnel, the facilities and the equipment necessary for such cooperation can best be assembled and maintained only in special centers. Existing hospitals are, of course, the logical places for cancer clinics. Certain minimum standards for these clinics have been established by the American College of Surgeons including, in addition to the personnel and facilities, provisions for accurate records and follow-up services. Approved hospitals of 100 beds or more have been urged to consider the formation of cancer clinics.

The organization of cooperative services is necessary to obtain the maximum efficiency in the diagnosis and treatment of cancer. The highly expert and specialized nature of the diagnosis, the surgery and the radiation treatment inevitably requires the concentration of such services in special centers. Last year the American College of Surgeons carried on its approved list 240 cancer clinics, 144 of which are integral parts of general hospitals.¹ The number of approved and approvable clinics is increasing. Anticancer activities on the part of state departments of health will no doubt result in the formation of more cancer centers under similar auspices. Cancer is now accepted as a public health problem of the first magnitude. All cancer patients, those who cannot meet the cost as well as those who can, should receive the benefits of the best that can be done for them.

1. Hospitals in the United States and Canada Conducting Cancer Clinics Which Are Approved by the College, Bull. Am. Coll. Surgeons 22:35 (Oct.) 1937.

At the recent commemoration of the twenty-fifth anniversary of the American Society for the Control of Cancer, it was emphasized not only that the formation of cancer clinics should be furthered but that special training should be urged for physicians who wish to devote themselves wholly to cancer in their practice. Such specially trained physicians will be needed increasingly to carry on the modern diagnosis and treatment of cancer in public and private institutions. At present, eleven hospitals offering in all only thirty-four positions are approved by the American Medical Association² for "residencies in malignant diseases." Of these hospitals, services of thirty-six months are offered by one, of twenty-four months by one, of sixteen months by two and of twelve months by seven. Obviously the existing facilities for postgraduate training in the diagnosis and treatment of cancer are inadequate, but they could be greatly increased by comparatively little effort. Time should not be lost in organizing thorough and comprehensive courses in suitable medical schools and hospitals. The National Cancer Institute Act, approved Aug. 5, 1937, provides for the training and instruction of qualified physicians "in all technical matters relating to the diagnosis and treatment of cancer." Evidently the framers of the act recognized fully the great need for such training.

TRANSFUSION OF MASSIVE DOSES OF CADAVER BLOOD BY THE CON- TINUOUS DRIP METHOD

S. S. Yudin,¹ first to introduce the use of cadaver blood for transfusion, has recently summarized the advantages of cadaver blood: (1) The amount of blood that may be obtained from a single donor is large; (2) it does not have to be paid for; (3) because of fibrinolysis which takes place in the blood of patients dying a sudden death, there is no necessity for adding sodium citrate solution; (4) the number of reactions is markedly diminished because of the absence of conserving fluids; (5) the Wassermann reaction is performed on the blood which is to be transfused, while the possibility of syphilis in a living donor is not always excluded, and (6) the necropsy which is performed on the cadaver before its blood is accepted guarantees the innocuousness of the blood, since it offers the opportunity of examining the donor for signs of tuberculosis, malaria, septic foci and secondary signs of syphilis.

The keeping of large reserves of blood for instant use in emergencies proved to be of definite advantage in the work of the Central Institute of Emergency Surgery at Moscow. Blood without admixture can be preserved

2. Hospital Service in the United States, J. A. M. A. 110:959 (March 26) 1938.

1. Yudin, S. S.: Drip Transfusion of Massive Doses of Cadaver Blood, Vestnik khir. 55, February 1938.

for longer periods than blood to which preserving fluids have been added. The number of mild reactions in 2,000 transfusions of cadaver blood amounted to 5 per cent. Yudin is convinced that the effectiveness of cadaver blood is not in any way inferior to that of blood from living donors.

The report of Marriott and Kekwick,² working in the Middlesex Hospital, London, on the results obtained from administering massive doses of blood by the continuous drip method in cases characterized by a severe acute anemia and a lowered regenerative hematopoietic function, stimulated Yudin to adopt this method in his employment of cadaver blood in a group of similar cases. His experience with twenty-five cases of advanced cancer gave exceedingly encouraging results. Patients who were the poorest risks because of advanced cachexia and profound anemia could be improved before the operation by massive blood transfusions. The method was likewise applied in twenty-five cases of profusely bleeding gastroduodenal ulcers.

The method presents certain technical difficulties, the principal one of which is the tendency for the corpuscles to sedimentate and block the drip bulb. Marriott and Kekwick have overcome this difficulty by bubbling a continuous stream of filtered oxygen through the blood, thus accomplishing a continuous stirring. Another difficulty is the not infrequent occurrence of phlebitis in the arm. According to Yudin, the introduction of 0.5 liter of blood raises the hemoglobin of an adult by 9 to 10 per cent. Gravely exsanguinated patients may be given the first liter of blood in fifteen or twenty minutes. However, the tempo of transfusion after that must be slowed. It is not advisable to raise the hemoglobin content more than 10 per cent every four hours. This concerns particularly patients who are not bleeding and patients with sclerosis and hypertension. Ordinarily, from forty to forty-five drops of blood is transfused every minute, or from 100 to 150 cc. every hour. Doses as high as 6 liters may be given in the course of two or three days.

Despite the exceedingly good results obtained with the method, Yudin does not feel that this is necessarily the solution of the problem. He believes that the same results may be obtained by what he calls the fractional method. Thus, a patient may be given 500 cc. of blood before the operation and from 1 to 1.5 liters after the operation in a course of one hour by the usual method. Additional amounts of 500 cc. may be given every succeeding twelve hours two or three times. He sees here another advantage in the use of cadaver blood, namely that it requires a lesser number of donors, thus giving greater assurance as to the compatibility of the blood than when the blood is taken from living donors.

INFECTIVITY OF CALCIFIED TUBERCULOUS LESIONS

Whether or not calcified foci from childhood infections with tuberculin are possible sources of endogenous reinfection in later life has been a disputed question for a half century. In 1884 Dejerine¹ studied calcified lesions in twelve tuberculous persons dying in the fourth, sixth, seventh and eighth decades of life. He failed to find tubercle bacilli in the calcified lesions. Material from four of these lesions was injected into guinea pigs with uniformly negative results. From these scanty data Dejerine concluded that the infectious agent disappears quantitatively from tuberculous lesions as soon as calcification is complete. Quite different results were subsequently reported by Rabinowitsch,² Schmitz,³ and others who tested the guinea pig infectivity of thirty-two calcified foci from human necropsies and obtained positive results in seventeen cases.

Doubt as to the reliability of previous conclusions was afterward expressed by Griffith,⁴ who found that in 176 trials chronic tuberculous tissues failed to infect guinea pigs, although acid-fast bacilli were readily demonstrated by animal inoculation. By animal inoculation Opie and Aronson⁵ demonstrated tubercle bacilli in apparently noninfected portions of tuberculous lungs, suggesting that the alleged infectivity of calcified foci was due to slips in technic or unavoidable contamination of the calcified area.

Since there is at present no unanimity of opinion as to the probable infectivity of chronic tuberculous lesions, Feldman and Baggenston⁶ of the Mayo Clinic restudied this problem with the latest technical methods. Necropsy material was obtained from sixty-eight persons ranging in age from 7 to 90 years who had died from causes other than tuberculosis. Evidence of previous pulmonary infection with tubercle bacilli was observed in all cases, the presumptive childhood tuberculosis appearing as encapsulated, caseous or calcified areas in the pulmonary tissues or the tracheobronchial lymph nodes. These encapsulated lesions were excised and emulsified in sterile sand and the emulsions thus obtained planted on two or more particularly favorable culture mediums. From two to six duplicate guinea pigs were inoculated subcutaneously with 1 to 2 cc. of each sample. All animals that died within twenty-one days were discarded, death presumably being due to primary or allergic toxicity of the emulsion or to nontuberculous virus or bacterial infection. The surviving guinea pigs were killed at the end of from eight to fourteen weeks and meticulously examined macroscopically, microscopically and culturally for evidence of tuberculosis.

3. Schmitz, Eugen: *Frankfurt. Ztschr. f. Path.* **3**: 88, 1909.

4. Griffith, A. Stanley: *J. Path. & Bact.* **32**: 813 (Oct.) 1929.

5. Opie, Eugene L., and Aronson, J. D.: *Tubercle Bacilli in Latent Tuberculous Lesions and in Lung Tissue Without Tuberculous Lesions*, *Arch. Path.* **4**: 1 (July) 1927.

6. Feldman, William H., and Baggenston, Archie H.: *Am. J. Path.* **14**: 473 (July) 1938.

2. Marriott, H. L., and Kekwick, Alan: *Continuous Drip Blood Transfusion*, *Lancet* **1**: 977 (April 27) 1935.

Positive results were obtained in only one of the sixty-eight chronic tuberculous foci studied. In none of the other foci was the presence of tubercle bacilli demonstrated by either cultural or inoculation methods. The authors concluded from this evidence that in the majority of cases the "primary complex" in tuberculosis passes through an involutional process unfavorable to the continued viability of *Mycobacterium tuberculosis*. In their opinion endogenous reinfection from definitely capsulated, sclerotic, caseous or calcified tuberculosis of childhood is unlikely to occur.

Current Comment

OUTBREAK OF GASTRO-ENTERITIS IN MILWAUKEE AND VICINITY

During February 1938, according to a report of the Wisconsin State Board of Health,¹ about 4.5 per cent of the population of Milwaukee was attacked by acute gastro-enteritis. The onset of an attack was usually abrupt and generally accompanied by nausea or vomiting and followed by abdominal pain, diarrhea or both. Vomiting usually subsided after a few hours, while diarrhea often persisted for from a few hours to a week. The stools of the patients had no striking characteristics. The incubation period, according to available evidence, varied from six hours to six days but most commonly was from one to two days. The outbreak apparently became definitely established about February 7 and waned after February 21. It involved surrounding communities as far north as Port Washington and as far south as Kenosha. Epidemiologic investigation served to eliminate in a reasonably satisfactory manner food and milk as a source of the outbreak. All the communities involved in the epidemic of gastro-enteritis with one exception obtained water supplies from Lake Michigan. The charting of the daily onset of the cases in relation to the turbidity of the water, raw water *B. coli* index, chlorine application, residual chlorine, wind direction, and similar factors revealed that the most unsatisfactory water condition existed during the period from February 11 to 14, when high bacterial counts, maximum *B. coli* index and maximum turbidity were reported. The outbreak coincided with the period of spring freshets; that is, the first heavy run off due to thaws and rains. This correlation pointed directly to increased pollution of the lake as the cause. The report concluded that the water facilities available in the city of Milwaukee at that time were inadequate for purification of water for an emergency of the kind experienced. Negligence could not be charged to the health and water works authorities, since chlorine residuals appeared ample at all times and the *B. coli* index of the tap water was well below the accepted treasury standards for a safe drinking water. Control of chlorination should be such as to assure at all times as effective sterilization as is possible with this process and to maintain the *B. coli*

index below the indicated maximum of 0.2. Tests for residual chlorine should be made at definite intervals throughout each twenty-four hour day and should be such that color and turbidity will not result in false readings. From a bacteriologic standpoint it appears desirable that present procedures be modified so that it is possible to obtain a lower *B. coli* index with individual samples than is given by present methods. Should the water fail to meet the suggested tentative standards, the health of the consumers should be further safeguarded by the boiling of all drinking water.

VISUAL STANDARDS FOR OPERATING MOTOR VEHICLES

Recognizing the increasing necessity for greater care in the operation of motor vehicles on the highways, the House of Delegates of the American Medical Association at the recent San Francisco meeting adopted the following resolution. The standards set forth were developed by the Section on Ophthalmology, where this program had been under consideration for many years:

Resolved, That the following be accepted as the approved American Medical Association standards:

A. For an Unlimited License:

1. Visual acuity with or without glasses of 20/40 Sn. in one eye and 20/100 Sn. in the other.
2. A form field of not less than 45 degrees in all meridians from the point of fixation.
3. The presence of binocular single vision.
4. Ability to distinguish red, green and yellow.
5. Night blindness not to be present.
6. Glasses when required be worn while driving and those employed in public transportation be provided with an extra pair.

B. Visual Standards for Limited License:

1. Visual acuity of not less than 20/65 Sn. in the better eye.
2. Field vision of not less than 60 degrees horizontally and 50 degrees vertically from point of fixation in one eye.
3. Diplopia not to be present.
4. Glasses to be worn when prescribed.
5. Coordination of eye, mind and muscle to be fully adequate to meet the practical visual road tests.
6. A limited license not to be issued to those employed in public transportation.

C. Renewals, Retesting and Reexaminations:

1. Renewals of license to be issued at least every third year. The applicant shall with each renewal make a declaration that he knows of no visual defect which has developed during the past year.
2. Retesting of acuity to be made at least every six years.
3. If any visual defects have developed, an examination by an ophthalmologist and the report thereof, to be required before reissuing the license.
4. License to state thereon the specific limitation for driving.

ORGANIZATION SECTION

MEDICAL PROBLEMS IN MINNESOTA

JAMES M. HAYES, M.D.
MINNEAPOLIS

This era of depression and recession with its political and economic upheavals has necessarily complicated medical problems in this as well as every other state in the Union.

We were fortunate in Minnesota in having one of the best state medical organizations before the depression. Through this organization we were able to control the hysteria which seemed prevalent when federal finances first came into the state for aid to the needy sick. Dr. Chesley says that, in his thirteen years as head of the National Public Health Secretaries Association, never before has he seen so much outside interference in the practice of medicine as he has during the past four or five years.

There are about two and a half million people in the state of Minnesota. One-half million, or about one in every five, are now on some degree of relief. Practically none of these people are able to pay for medical care. About 50 per cent of them live in the rural communities, the other 50 per cent in the large cities.

Unfortunately the Twin Cities had long ago established the precedent of caring for the indigent sick without remuneration to the participating physicians. These are cared for mostly in the charity hospitals. In the past the burden was not so great, but the depression has made this burden almost unbearable. This situation should be changed, but so far the physicians have made no effort to have it changed and the public willingly accepts this free service. The same situation had existed in Chicago, but in 1936 the physicians there received nearly half a million dollars for their services in caring for the indigent sick.

In the rural communities the proportion of indigent is so great that it would be impossible for the physician to survive if he did not receive some remuneration for the care of these indigent sick. Accordingly, a minimum fee has been established for the care of these patients in the rural districts.

Our state medical association, as well as every unit throughout the state, feels that it is our duty to render to every sick person the best possible medical care regardless of his financial status.

Since federal aid first came into the state at the beginning of the depression, federal, state and county committees have spent many hours in an attempt to work out plans for the most efficacious care of the indigent sick.

Last year federal funds ceased to come in for direct relief. Since then the county, with assistance from the state, has taken care of all direct relief patients. The Works Progress Administration, a federal project, still exists. Those on direct relief who are able to work may be employed by the WPA. They receive a fixed salary from the federal government; this usually covers ordinary medical care. On Dec. 31, 1937, there were 182,896 individuals employed by the WPA. Other

federal agencies are the Farm Security Administration, National Youth Administration, CCC camps and Veterans Administration. The Farm Security Administration is making plans to finance medical care in connection with farm security loans. At present there are about 34,000 such persons in this state. Under the National Youth Administration, supplemental medical aid may be granted by county boards from direct relief funds in case of need. At present there are about 13,651 such youths. The CCC camps are taken care of medically by army medical reserve officers assigned to these camps and paid an annual salary. At present there are about 9,000 in such camps. Under the Veterans Administration the medical care is in charge of the Veterans Bureau. Those with service connected disabilities or, if indigent, with non-service connected disabilities, are cared for at federal expense. This one service is, unfortunately, much abused. There are about 11,000 now under such care.

The State Relief Agency is responsible for all those on direct relief. Up to about one year ago federal funds were available for this purpose, but since that time this relief has been administered by the eighty-seven county welfare boards of the state. The county funds are supplemented by state funds as determined by the State Relief Agency and the county boards. On Dec. 31, 1937, there were 152,854 on direct relief.

The State Board of Control is one of the important state agencies. This board has charge of the social security aids to the needy with the exception of federal old age assistance, unemployment compensation, maternal and child health services, and public health. Specifically, this board directs old age assistance, aid to dependent children, aid to the blind and services to crippled children. Funds are supplied by the federal government either outright or in matching state funds. Old age assistance is a monthly cash payment. The maximum amount per person is \$30 a month. This is paid only to the needy of 60 years or over who do not qualify for federal old age benefits. The county welfare board ordinarily determines who shall be granted this assistance and may be called on for financial assistance in emergency or special medical care. There are about 62,357 such persons in the state at this time. Mothers' aid and aid to dependent children is given when the county welfare board determines they have no other adequate means of support. There are at present 11,512 mothers and children on such relief.

The State Board of Control dispenses special funds for the care of children in need of specialized care. This fund is available only for children with special physical or mental diseases which may be benefited by special treatment. The state board may and often does use private charities of various kinds in the care of these patients. Aid to the blind takes the form of a monthly cash payment. The degree of blindness as well as the financial status of the patient determines the degree of financial assistance. The County Welfare

President's address, read before the eighty-fifth annual meeting of the Minnesota State Medical Association, Duluth, June 29, 1938.

Board, with the assistance of a special ophthalmologist, determines who shall receive this assistance and how much. Nearly 500 out of 3,300 blind in Minnesota today receive such assistance.

Perhaps no class among the indigent sick or disabled receive more attention and adequate special care than do the crippled children. Dr. Hilleboe, the medical man

on the State Board of Control, has supervision of this as well as all other medical work under this board. It is estimated that there are nearly 10,000 crippled children under the age of 21 in Minnesota today. Everything known to medical science is employed in the care of these patients to cure them and render them useful citizens. Diagnostic clinics are held throughout the state at accessible points, where diagnoses, consultations and follow-up examinations may be made. Public health nurses are sent out to assist in every way possible. They help to locate new cases, organize clinics, administer physical therapy when directed, and see that the patient carries out specially prescribed treatment. The State Board of Control provides medical and hospital care for these patients from a special fund.

All state institutions come under the supervision of the State Board of Control. These include the feeble-minded, of whom there are 2,320; the insane, numbering 5,684; the tuberculous in county and state sanatoriums, 2,097; the Gillette State Hospital, now containing 221 patients, and the colony for epileptics, of which there are 1,104.

THE MINNESOTA DEPARTMENT OF HEALTH

The Minnesota Department of Health confines its work largely to prevention and control of disease. In carrying out this duty, it is necessary to train a large personnel who supplement and assist in the work of the practicing physician to a high degree. Through this organization the practicing physician is able to increase his efficiency in preventive medicine. To promote maternal and child welfare, postgraduate courses are held throughout the state. These courses are given by physicians highly trained in these specialties. The public health nurse comes in here to great advantage in assisting at these clinics and collecting the mothers and infants who especially need attention. The Public Health Department has long done yeoman service in the prevention of disease. Recently its efforts have increased many times. It

has made it possible for physicians from all parts of the state to have all cases of pneumonia readily typed and, when possible, furnish serum for the treatment of this disease.

In conjunction with other medical organizations of the state, it has entered into a program of public education and control of venereal diseases. With renewed vigor it has promoted diphtheria immunization, small-pox vaccination and typhoid control. In combination with other health and medical organizations, it has established a program in Minnesota for the education of the public and the care of tuberculous patients that cannot be surpassed by any other state in the Union.

In addition to the federal, state and county agencies for medical care and prevention of disease, we have several important private agencies.

The Public Health Association collects large sums of money through the sale of the Christmas seals. These funds are used chiefly in the prevention and control of tuberculosis. They supplement the work of the aforementioned organization in tuberculosis work.

The Woman's Field Army for the Control of Cancer, together with the Cancer Committee from the State Medical Association, sponsors a program for public education in the need for early detection and treatment of cancer. The Association for Crippled Children and Adults sponsors a program for education concerning needs of crippled children and adults, particularly for training in handicraft.

The American Legion and Auxiliary are doing much in aiding the underprivileged child. They are just now sponsoring a campaign of educating and persuading the veteran to have a yearly physical examination.

How the relief dollar is spent in Minnesota. Statewide direct relief, year of 1937, \$11,423,379.73; drought relief \$215,827.48 is in addition to this amount.

Parent and teacher associations conduct a summer round-up of preschool children. Under this program these children receive a physical examination, and defects thus discovered are corrected if possible.

In listening to this discourse, one would naturally think that we have many overlapping agencies. Perhaps it would be simpler and possibly more efficacious to have all this health and medical work under a single supervisor.

Most of these organizations have been in existence for some time. Each has had a personnel trained for special work. Each has fitted well into the general plan now in operation. All are cooperating now with such a high degree of efficiency that perhaps no state in the Union has a better plan for caring for the indigent sick or disabled.

Amount Spent for Luxuries and for Medical Treatment

Motor car	\$150.00
Tobacco	67.00
Candy	37.00
Drinks and chewing gum.....	34.00
Radio and music.....	25.00
Physicians' fees	24.00

All will agree with me that, in the last analysis, matters of prevention and cure of disease must be directed and controlled by the practicing physician. The responsibility of direction and control of all this work must necessarily fall on the shoulders of our state medical association. To those who have held the reins in this organization in the past, credit must be given for having perfected this organization to the point at which it has been able efficiently to cope with all these difficult problems. We are convinced that little could be desired in improving the friendly cooperation we receive from all other organizations who take any part in the prevention and cure of disease.

The University of Minnesota, through its regular medical staff, has given much assistance to the practicing physician. The unique establishment of the continuation course in medicine at the university under the direction of Dr. O'Brien has been especially comforting to those who wish to go back to school and increase their knowledge of the latest developments in medical science.

So far I have spoken almost entirely of the indigent sick. Much has been said of the neglect of the near indigent or the low income group. Those who thus complain usually know little of the actual situation in the medical care of this class.

In Hennepin County we have established the so-called Medical Service Bureau. The main purpose of this organization is to care for any of this class whose income is just above that of the indigent class. This is an adjunct of the Hennepin County Medical Society. Members of the Hennepin County Medical Society have expressed a willingness to care for these patients for whatever they are able to pay. All relief agencies, charity hospitals or other charity organizations are requested to refer to this bureau any patients who apply for free medical care but who are not eligible because their income is slightly above that required for eligibility. During the years 1936 and 1937 only 147 patients applied to this bureau for care. The great majority of those thus referred went back to their family physicians, by whom they had been taken care of for years for little or no financial outlay. Contrary to reports, these patients are charged very little by the physician and they usually take plenty of time to pay, so that the burden is not so great as some informers would have it appear.

Complaints have been registered that portions of the state are inadequately supplied with physicians. A few years ago complaints came from the northern part of the state that certain patients in that area had died because they were unable to obtain medical care. This complaint came to the State Board of Control and was

passed on to us. A committee from the State Medical Association was sent to Bemidji one Sunday to investigate the situation. We called in physicians and others concerned. We found that none of these patients had suffered because of inaccessible physicians but rather because they did not avail themselves of the medical care at hand or refused to follow medical advice given them.

Even in the most isolated areas, physicians never failed to go when called. One of the cases cited was that of appendicitis. The patient visited the doctor and was advised to go to the hospital. Instead, he went home and failed to call the doctor until he was on the verge of death. In another instance the patient had diphtheria and failed to call the doctor until late complications had set in. The doctor visited him and administered antitoxin but the patient died as a result of complicating diseases.

We were unable to see how any other possible distribution of physicians could have given any better results.

Recent reports of the Committee on Costs of Medical Care, the American Foundation for the Study of Medical Care and the Committee of 430 Physicians have given the public the impression that the medical profession is having dissension within its ranks. Of course there is always some dissension, but this is

Agencies Interested in Medical Aid in Minnesota

<i>State Relief Agency</i>		

mostly because those who have never really treated the sick have taken it on themselves to tell the practicing physician how to practice. Some of the farm papers of the state have taken these remarks seriously, thus adding fuel to the flame. A radio speaker in Wisconsin, representing labor unions, spread the news over that state and Minnesota that the Committee on the Costs of Medical Care has shown that 46 per cent of those with a salary below \$1,200 and 42 per cent of those

with a salary below \$2,000 receive no medical care. Their information is false and misleading in that they have not shown need for medical care in these people. If some of them had practiced among these people they would realize that they usually have medical attention when they need it. I think I can frankly say that the majority of physicians in this association practice among this class the greater part of our time and know that these statements are false. Critics have not shown and cannot show that, under the panel system of England or any governmental system of medicine, do people in this class apply any more readily for medical care. The average physician knows that the patient does not stay away from the doctor because of cost but rather from negligence or fear of being told he has some serious condition.

The Minority Report of the Committee on the Costs of Medical Care indicates the impracticable suggestions of the Majority Report. The Majority Report gives the public the impression that the physician is receiving this large amount of money, when in reality this amount includes the cost of hospitalization, nursing care, dental care and all expenses entailed by the sick patient. An analysis of their figures shows that the physician received only 29.8 cents of each dollar. If they had given a comparative study of other expenses and especially that for luxuries, their conclusions would have seemed more just.

Dr. Scammon of the University of Minnesota has made such a study, which shows the amount spent by the average family per year for luxuries as compared to medical expense.

In addition to this, 125 million dollars is paid annually to various healers other than physicians, and 350 million dollars for "patent medicines." He has also shown that state medicine in Minnesota alone during the year 1934 would have cost \$20,000,000, or one-half the entire state tax levy.

Germany today has a completely government controlled system of medicine. The death rate in Germany is 12.3 per thousand of population, while in the United States it is 10.7 per thousand. Today 40 per cent of

the money paid out for medical care in Germany goes to politicians or lay supervisors, while only 60 per cent is received by the physician, who must assume all the responsibility for the care of the sick patient. Patients taken care of under this system will readily say they do not desire it, and statistics show that patients do not go to the physician any more readily than under our system.

The various committees mentioned have obtained their information from improper sources and therefore have arrived at incorrect conclusions.

The Board of Trustees of the American Medical Association has instituted a general medical survey of the entire United States. This survey is of great importance because it is being conducted by the only group of men capable of making such surveys of any value.

The practicing physician with the county as the unit will give the best possible information. This survey has already begun in the various counties of this state and the response from the physicians is encouraging.

There are always a few in this profession, as in other walks of life, who are anxious to try some new experiment. Those who favor government control of medicine know little of the actual working of government medicine from the point of view of the sick or the cost to the government. The so-called Medical Guild, or the system under which we practice medicine today, has existed for over 500 years. It has withstood the attacks of ambitious politicians and other outside aggressors and has satisfied the properly informed man that no better system has yet been proposed.

There is nothing in this system that will not lend itself to the most scientific advances, nor will it in any way prevent us from accepting any reasonable outside assistance from the federal government or from philanthropic individuals or organizations. We do not claim anything like perfection in this system, but we do defy any other profession or group of individuals to show greater activity in an attempt to better their work individually or as a group.

953 Medical Arts Building.

BEWARE OF FALSE GODS!

An Editorial from the Kansas City Medical Journal, August 1938

If you are not familiar with the impending investigation of the A. M. A. at Washington, it is just that you have not read the recent issues of your own J. A. M. A. or you have not picked up the papers from the front lawn. The build-up of the government to dissipate and dilute the influence of the A. M. A. is showing progress in all directions. Members who have never participated in the organization and progress of the medical profession have been uncovered and minority groupings in different thought channels have been encouraged to display their antipathy. The barrage has been amplified by attacks from different bureaus and departments of the government. The scare and the threat of the law and the grand jury has not been overlooked.

The unfortunate part about the present situation is that while all of these attacks have some small elements of fact, when combined they tend to obscure the great values for the good of the whole people which organization in the profession has established. Enough wolves nipping at the heels and annoying a strong man will wear down any enthusiasm for existence.

One may declare a vacation for tradition for a period of time. One may wink at ethics for another period. One may argue that public policy demands a cessation of standards. Some

may insist that it is not necessary to balance the science and the art of medicine. There is no doubt but that you can tear down the structure of better and honest medicine in America if the fitness of change in the house of medicine is not judged by the profession itself. It is notorious that laymen are not able to choose medical attention or rather health attention by any measure of their judgment.

Only as the medical profession, through organized medicine and the A. M. A., has erected standards of medical education, eliminated quackery, qualified specialists and criticized hospital methods, etc., has the quality of medical practice of America developed. There has never been any police power to the A. M. A. There have never been any laws conferring any measure of penalty or legal action by the A. M. A. There has never been any big boss such as other groupings in business and sports have devised.

All of the progress of American medicine has been through the better education of physicians, through the moral persuasion of the Councils of the A. M. A. and through the traditional application of ethical standards. Such means are bound always to have more weight than mere laws. Public opinion has supported these various items of progress and gradually the quackery and charlatanism of America has faded into disrepute.

Medical schools with their huge establishments may feel that they are peculiarly fitted to practice mass medicine with governmental subsidies. Large non-profit metropolitan and even smaller hospitals may feel that they are ordained through the merit of their physical establishment to be the center for medical and health needs of their communities.

These modern factors of civilization and progress are prone to forget that it is really the personality and peerage of their medical staff that establishes their fame and their clientele. It is now apparent that even the physicians who staff such institutions sometimes arrogate to themselves an unusual ability to serve the people. Physicians in groups promptly believe that in their small union rests the *locum tenens* of Aesculapian lore.

All these things may be true. But one must realize that only a small minority of all the people can take advantage of such institutions and such groupings. The great majority of people

scattered over the country must be taken care of by the physicians of their locality. The quality of such medical care can only be maintained by supporting the progressive type of physician who keep up with the times and who does not indulge in unethical methods or tamper with traditional items of good medical manners. It is further maintained by a better distribution of well educated physicians.

These factors of medical progress are maintained by the inherent good will and the promotion of better standards by the Councils of the A. M. A. and other national medical organizations. If you dissipate the influence behind these standards, you are cutting out the foundations that are responsible for better medicine for all the people in America. One should not listen to the sirens who will cheer on those who are willing to scuttle the ship. Hold fast to those things that are good! Beware of false gods!

E. H. S.

HEALTH PROBLEMS IN EDUCATION

SECOND SYMPOSIUM, HELD AT SAN FRANCISCO, JUNE 14, 1938

DR. ROBERT T. LEGGE, BERKELEY, CALIF., IN THE CHAIR

The Second Symposium on Health Problems in Education was arranged by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, with the cooperation of the following sections of the Scientific Assembly of the American Medical Association: Section on Pediatrics, Section on Ophthalmology, Section on Laryngology, Otolaryngology and Rhinology, and Section on Preventive and Industrial Medicine and Public Health. The first symposium on Health Problems in Education was held during the annual session of the American Medical Association at Atlantic City in 1937 and was attended by approximately seventy-five persons, mostly physicians. The second symposium was largely attended by teachers and school administrators, some 300 in all.

The speakers presented their own opinions. These do not represent the policies of the American Medical Association, except as they coincide with the policies of the Association expressed by the House of Delegates.

Abstracts of the papers presented follow. The discussions have been omitted. Complete papers, and copies of the discussions so far as they were submitted in writing by the speakers, will be furnished in mimeographed form, gratis, to physicians and educators on application to the Bureau of Health Education of the American Medical Association.

LOOKING BACKWARD IN THE SCHOOL HEALTH FIELD

THOMAS D. WOOD, M.D.

Professor Emeritus of Health Education, Teachers College, Columbia University;

Chairman, Joint Committee on Health Problems in Education
NEW YORK

Foundations have significant value for edifices built on them. School health work is of comparatively recent development. Greeks and Romans had ideals of sound mind in the sound body which have not been surpassed, perhaps not been equaled. The Middle Ages produced nothing significant for adequate recognition or care of health. School health work is a nineteenth century, Old World development beginning in France in 1833. Significant progress was made in Wales in 1848 in the school lighting and ventilation and the appointment of a medical attendance officer. Later contributions were made in 1866 in Breslau and in 1874 in Brussels, where the first system of med-

ical school inspection was established. School health work in America began in Boston in 1875 with records of height and weight. In 1877 dental service was established in Belgium; in 1822 the first school physician was appointed in Egypt. The first school nurse was appointed in England in 1887 and the first school physician in 1891. A regular system of medical inspection was established in Boston in 1894, and New York appointed 134 school physicians in 1897. Local boards of health controlled and administered the early school health work. Wiesbaden in 1896 organized a very comprehensive program of health work in the schools. School health work was promptly accepted by parents. Connecticut in 1899 passed the first state law requiring teachers to test eyesight every three years and since that time many states have passed laws relating to school health services and health education, but many such laws have ended in futility because the funds were not provided for very effective administration. Commercial organizations have attempted to utilize school systems for commercial purposes, but some worthy contributions to school health education have been made, especially by life insurance companies. Special contributions from voluntary sources include those by the American Child Health Association, the White House Conference on Child Health and Protection and the Joint Committee on Health Problems in Education.

RELATIONSHIPS OF HEALTH SERVICE IN THE SCHOOLS TO HEALTH EDUCATION AND THE GENERAL CURRICULUM

EDNA W. BAILEY, Ph.D.

Associate Professor of Education, University of California
BERKELEY, CALIF.

One of the impressive facts about the practice of medicine is the indisputable authority of the physician in relation to his patients. Wherever the physician sits, there is the head of the table, no matter if the table be education and not medicine. Thoughtful and competent physicians do not feel themselves to be experts in all the fields. Able men and women in education do not count themselves authorities in medicine. There is an awakening to the significance of the relationships of health service to all other school activities. Health service is still the alien aristocrat, miracle working, incomprehensible, to be handled only with careful insulation against its powers. If health personnel should be admitted to a real share in educational enterprise, education might be exposed to shocks and changes of a most disquieting character. Recent studies by the Joint Committee brought forth emphasis, especially by parents and school executives, for the need of medical judgment with regard to health education, especially the choice of topics, validation

of information, and maintenance of sane balance. Relationship of health service to health education is to build up an appreciation of medical, dental and nursing care. Definite and specific instruction is the purpose of procedures in the school health service. School physical examinations may be provided for the purpose of getting everybody examined or as an educational demonstration involving a few volunteers. A usable vocabulary of health terms is necessary in general health education as well as in sex education, where its importance has been demonstrated. Health service must include the private physician as well as the public health worker. Close relationships between medicine and education are of far-reaching significance. In our schools, future citizens may be taught the dignity, worth and incalculable human usefulness of the art and science of medicine, by intelligent cooperation between the physician and the teacher. In the physician's office and at the bedside of his patient, the physician may learn wherein schools are doing right and beneficial things for children and wherein they are making sorry blunders.

THE PHYSICIAN'S CONTRIBUTION TO EDUCATION

The Educator's Point of View

GEORGE A. RICE
Principal, University High School
OAKLAND, CALIF.

There is no even, regular contact between the physician and most of the people. Few school children can name a family physician. For many years educators have been saying that health is one of the goals of education, but they have done little about it. I know of no adequate health program in a public school today. Physicians need to know more about schools. Many services can be given by schools to students with health handicaps. One such is a convalescent room with beds, lounging chairs and other conveniences, with a teacher in charge; such a room is to be found at University High School, Oakland. Many physicians make use of this to get children back to school, but not on the regular program, more quickly. The most important factor in the health service is the interest teachers have taken in health. Teachers can be taught to find the most obvious health handicaps, but how to work out the machinery for the care of handicapped children is another matter. In University High School, students are referred to the convalescent room from the following sources: attendance office, classroom teachers, students themselves who fear they have weak hearts or tuberculosis, school physician follow-up, parents direct, candidates for health certificates for extracurricular activities, such as athletics, and from school officials who wish to protect the school against liability for injury to students engaged in activities connected with the school. Out of the health service program has grown a surprising list of adjustments that may be made in the school load: short days, light academic programs, lightened extracurricular programs, modified physical education programs, modified school routines, modified classroom procedures, lightened assignments of work, financial assistance, delayed graduation. About 30 per cent of the boys and 45 per cent of the girls are referred to the convalescent room. A report by letter is made to physicians of the activities of the school, curricular and extracurricular, and the physician's advice as to modifications for his patient is asked. Physicians are using these opportunities frequently and helpfully. Physicians give more information than they formerly did to the school, stating not only a wish that a student be excused from physical education but giving information on which to base a modified program; this does not mean disclosing any information which should be privileged. Cooperation between the school and the private physician has been promoted by establishing and maintaining ethical relationships. The school never makes a contact with the physician without the consent of the parent. No child is ever programmed for an activity which a physician has said might be harmful. The school never recommends a specific physician. Physicians and schools are both concerned with the health of children. Has not the time come for a more cooperative attack on the problem?

THE PHYSICIAN'S CONTRIBUTION TO EDUCATION

The School Physician's Point of View

ARTHUR E. WADE, M.D.
Director of Health, Seattle Public Schools
SEATTLE

Children become adults. Never before has youth needed such rigid preparation for life. Educators are concentrating all their abilities and mobilizing all their forces in an effort to meet this exigency. Vocational schools, special schools for the physically handicapped and guidance departments are being instituted and the recognition that health is prerequisite to learning has become accepted. The medical profession has been asked for contributions to this work and is responding. Full-time health departments exist in the public schools of larger cities and part-time medical services in the schools of smaller cities. School physicians have been in the schools for forty years. The full value of their contributions and their degree of success depends on interest and cooperation by the medical fraternity. Special schools exist for sight saving, hard of hearing, open air, crippled children, opportunity, slow moving, and home teacher. Social and educational misfits call for individual guidance and counsel. The objective is that status which results from a healthy body, a clear thinking mind and a fund of knowledge concerning one's environment which may be used for personal comfort and social, business or spiritual success. In medicine, as in education, the whole individual is considered and the ultimate goal in both is successful living. Education and medicine have developed independently but have come together in final conclusion. Without controversy these two professions should now unite in complete understanding and with loyalty to a common cause. During the forty years in which doctors have assisted the schools their contributions have developed from sanitation and contagion to include physical defects and their follow-up toward correction, and now it is recognized that physical strains, especially those of physical education, might cause injury to some children. A new type of physical examination is designed for the appraisal of physical capacity. The health of children is in the hands of physicians. The school physicians and the school nurses, as a transfer of qualified physicians and nurses from private practice to school medicine, are a contribution from the medical fraternity. They are representative of the medical profession and to them is given a tremendous field of privilege. School medicine is becoming a specialty for which young men will soon train; graduate courses are now appearing in a few medical schools. It is of vital importance to the medical profession that qualified personnel carry to youth in the schools a modern and authoritative health program. Physicians in every community should answer the educators' invitation by exhibiting personal interest in the schools. School health departments need no longer operate under the personal opinions of individual health directors or under the prejudices and customs of local communities. Studies have been made by the White House Conference on Child Welfare, the American Academy of Pediatricians, the American School Health Association and other groups. School medicine is rapidly taking a position of supreme importance as the only agency through which state health laws, public health and private physicians can communicate with the schools regarding the physical welfare of school children. School medicine is the physicians' contribution within the schools. The private physicians' professional services and advice relative to health and mental capacities of the pupils are their contributions outside the schools. The work should be divided into two fundamental divisions:

(a) What shall be performed within the schools:

1. All services which render the schools safe places for children.
2. Assistance in the control of infectious diseases.
3. Periodic health examinations of pupils.
4. Administration of first aid.
5. Preathletic or physical education examinations.
6. Supervision of subject matter in health sources.
7. Counseling with all health groups akin to the schools.
8. Conveyance of medical information to the schools.
9. Consultations relative to alteration of individual school programs.

(b) What shall be performed outside the schools:

1. All complete diagnoses, with view of treatment.
2. All treatment, except first aid.
3. All family and personal physician consultations.

The inference in this division of services is that the physician's contribution to health education is best delivered when a division is harmoniously agreed on whereby the private physicians conduct outside the schools all treatment except first aid and the schools conduct all services in making the schools safe places, in establishing healthful living, and in assuming the responsibility for health education of children. The educators have requested the physicians to unite with them in the preparation of youth for life. The physicians are responding. Their contribution is formulated. It only awaits final agreement on methods of administration before it becomes unleashed to fulfil its mission in placing the powers of physiologic youth at maximum receptivity and development.

THE PHYSICIAN'S CONTRIBUTION TO EDUCATION

The Practicing Physician's Point of View

BURT R. SHURLY, M.D.
DETROIT

Since the Civil War an expansion of educational opportunities has been witnessed for each generation. It was formerly unusual to find a college graduate. Now college has become the ordinary expectation of a vast number of boys and girls. The medical profession was for many years in advance of the average sphere in education of the rank and file of our people. The old family doctor had great influence with his clientele in the determination of the choice of a vocational career. He was a preceptor, guide, counselor, friend and beloved companion of the young people. He had their confidence and respect. His influence extended to the church, to public officials, to school teachers, and to public health when no health officer existed. With the inroads of specialism, the old influence waned and has been succeeded by the newer psychology, where the specialist knows what he knows and may know little else as it applies to the progressive requirements of education and to the broad cultural fields of modern life. Where we find a practicing physician serving on the school board, we find a valuable asset to the educational field. The physician can fit into the picture and produce an enormous amount of good in counseling and outlining the daily physical care of the school child. His function as an observer of life with broad common sense and scientific knowledge can have widespread applications. Schools are responsible for the child only during school hours, but these comprise a considerable portion of the day. Ethical problems, such as relation of the family doctor to the school authorities, include the consideration of the practicing physicians and the parents.

The Detroit school system maintains a special card index for each of the 286,000 pupils in its public schools. This blank card is sent annually to every parent, asking for the name, address and telephone number of the family physician; between 70 and 90 per cent have complied. Two members of the school board are physicians and surgeons, one member is the father of a physician and another is the son and brother of a physician. School doctors and nurses are appointed by the department of health, but a splendid working agreement exists without friction. The practicing physician whose name is on the pupil's card must not have his family taken away from him by any interference or advice given without consultation with him. He is entitled to participation in all discussions regarding the child's health. It is of paramount importance that contagious or infectious diseases be recognized in their earliest stages. Teachers cannot be diagnosticians, but they can note pupils' symptoms, such as fever, sore throat, nausea or vomiting, rapid pulse, chills, bad breath, lassitude, malaise or other symptoms. The child is sent home, to be seen by the family physician, who in many instances has already vaccinated the child against smallpox and used other preventive measures which have been found of value. By cooperating with the

family doctor, he is made a sympathetic adviser. The medical profession, like the great human family in general, has its percentage of cranks, extremists, men without scientific ideas and those who have allowed notions to encroach on their qualities of good sense and medical balance; these become special problems in diplomacy, and herein lies the value of a complete understanding between the practicing physician and the school authorities. When and where such an understanding exists, the practicing physician is making a great contribution to education. One of his major contributions is the encouragement of periodic health examinations for all pupils in the schools. He can further throw his support behind programs designed to improve the diet of school children and to further the employment of tuberculin testing, x-rays, and other methods for the early detection of disease. Education is constantly being challenged by those who wish to reduce taxes, regardless of the cost in human welfare and human happiness. Widespread education is an absolute necessity if democratic society is to persist. Much can be contributed to education by mutual understanding between the practicing physician and the principals and teachers.

BETTER VISION FOR SCHOOL CHILDREN

C. S. O'BRIEN, M.D.
IOWA CITY

Care of the eyes with conservation of vision is an important health problem in college students. During this educational period though, many young people discover that all is not well with the visual organs; poor vision and other signs of eye strain often appear for the first time. In a recent report by the Eye Health Committee of the Student Health Association, it is stated that of 1,250,000 college students in the United States an estimated 15 to 25 per cent enter college with more or less serious ocular defects and many more develop during the college courses. In most schools there are no particular visual requirements. Even when a physical examination is made the examination of the eyes is quite cursory, discovering only gross defects; for example, myopia, high degrees of astigmatism, congenital anomalies and advanced diseases of the eyes. Hyperopia, moderate astigmatism, muscle imbalances, disorders of accommodation or convergence and other defects which affect sustained close work were not detected. In many colleges and universities little attention is given to the lighting of dormitories, fraternity houses, sorority houses, libraries, classrooms and laboratories. No attention is ordinarily paid to the instruction of students in conservation of vision with special relation to eyestrain, adequate lighting and proper posture. Admittedly utopian is the idea of a complete examination of the eyes, with refraction under a cycloplegic for all entering students and at the beginning of each successive school year. In addition, the pupils should be educated as to proper lighting, posture, symptoms of common eye defects, muscle imbalances and general care of the eyes. A beginning, no matter how small or apparently insignificant, should be made toward such a goal. It might be made by the universal adoption of a standard visual test for all entering students and its repetition each year. If all schools adopted the same type of Snellen chart, a common distance, and standardization of the illumination at from 7 to 10 foot candles, data would soon accumulate which would be of value in statistical studies and in the determination of further steps in ocular conservation. Such testing could be done by a physician or by a trained technician. It could be carried out by almost any school. The next step is one which many schools could easily take but which many more would find difficult; that is, an external ophthalmoscopic examination of the eyes, which must be made by a physician who has had ophthalmic training. The desired end is a complete examination of the eyes, including refraction under an adequate cycloplegic by a trained ophthalmologist. At present only a few schools could do such a thing, namely those with a college of medicine, with a strong department of student health or with adequate funds to employ trained ophthalmologists. An alternative is a requirement that each student present as a part of admission creden-

From the Department of Ophthalmology, State University of Iowa College of Medicine.

tials a certificate of recent date from a competent ophthalmologist setting forth the condition of the eyes. For those who could not otherwise afford it, the examination could be made by a physician employed by the school. Accurate records should be kept of all tests. If lighting is inadequate, measures should be taken to rectify such defects in libraries, classrooms and laboratories as well as dormitories, fraternity and sorority houses and rooming houses in general. Two or three easily understandable lectures might be given to entering students on simple ocular hygiene and the requirements for adequate lighting; thus students could be made to understand the symptoms arising from defective eyes and the importance of conservation of vision and reasonable care of the visual organs.

HOW SHALL SEX BE TAUGHT IN THE SCHOOLS?

THURMAN B. RICE, M.D.
Professor of Bacteriology and Public Health,
Indiana University School of Medicine
INDIANAPOLIS

It is expected that the schools shall help the home to prepare the child for the problems of life. The most difficult and important problems in life are those which have to do with sex. A large percentage of marriages are unhappy and many of them end in separation and divorce; many young people do not know how to go safely about the important project of choosing a marriage mate; sexual perversion is apparently on the increase; illegitimacy and criminal abortion are all too common. It would be better for one to fail in everything else and to succeed in his home life than to succeed in everything else and fail in his home life.

Sex must be taught as a pure, fresh, wholesome and perfectly legitimate phase of life. We are not required to apologize for it. There is but one place where sex is best taught; that place is the home. Mothers and fathers who do not accept their obvious duty in this respect are guilty of very serious neglect. The instruction of the child should begin long before he or she starts school by answering truthfully, all questions and by correct habit formation and the building of good mental and moral patterns as a by-product of wholesome home life. Many homes will not as yet accept that responsibility.

Perhaps the church should step in, but many who need such instruction have no church connection and in many churches instruction is merely to "behave oneself." Y. M. C. A.'s, Y. W. C. A.'s and other youth groups reach too few persons and at too late an age. The schools then must undertake this function but will probably never do it really well because it gets the children too late; it must teach children of the widest variety of cultural, ethical, economic, moral and religious backgrounds; it will run at cross purposes to the teaching of the parents and spiritual advisers; a very large proportion of the teachers are unmarried persons whose understanding of sexual problems is either academic or illicit; there are two sexes to be taught and two sexes to do the teaching. Schools should teach sex only because it is absolutely necessary and because no other agency seems to be doing it.

Sex education should be integrated throughout the entire school course and on the basis of home life as a unit which will allow sex to be taught through arithmetic (home budgets), geography, history, nature study, science, physical education, agriculture, gardening, economics and hygiene. It must be suited to the age of the child and as far as possible individually, and great care must be taken not to whet the appetite. Students should not be unnecessarily and conspicuously separated on the basis of sex for the purpose of giving sex instruction. Sex instruction must never be morbid with relation either to pain and danger of childbirth or to danger of disease. Mere anatomy and development of the reproductive organs is not sex education at all. The emotional side of the subject must not be neglected. The individual who regards sex from the proper emotional angle can almost always be trusted. Sex education cannot answer every question but must show the child the way to learn the truth about so important a matter. Adult education in matters pertaining to sex is important and can be handled through mothers' groups, parent-teacher associations, night classes, extension courses and the

like. The school must seek only to supplement the home. It must avoid taking this subject away from the parents but rather it must merely bridge the present gap until the home is able to take up its normal and logical responsibility.

QUALIFICATIONS FOR TEACHING HEALTH

THOMAS A. STORY, M.D., PH.D.
Professor and General Director of Hygiene and Physical Education
STANFORD UNIVERSITY, CALIF.

The health of the individual as a whole is a combination of essential somatic, mental and social qualities of living. By somatic health I mean body health including normal growth, development, competence and comfort. By mental health I mean the service of a normal, adjusted, orderly, satisfied, happy, joyous, vigorous mind. Health is taught for two main purposes; to present information to the individual and for the formation and practice of wholesome healthy habits with particular reference to the age involved, the health of his family and the health of his community. Some of the critically important periods in the life of the individual where he should be taught health with a special emphasis include (1) when marriage is contemplated, (2) when parenthood is expected, (3) in early infancy, (4) in the preschool period, (5) during the elementary school period, (6) in the secondary school, (7) in college, (8) in professional school, (9) when the individual is not in the home or in school and (10) during adult life.

Those who teach health nowadays include: (a) friends, neighbors, the gang, the prospective mate, (b) the man in the street, (c) the movies, theater, radio, books, articles, newspapers, magazines, advertising matter, (d) the family, (e) cultists, faddists, quacks, (f) clergymen, (g) family doctors, (h) self-appointed advisers, (i) school instructors, (j) drug store clerks and others. In the various periods of life different influences come to bear, but at some time or other practically all of those mentioned influence the health conduct of the individual.

The qualifications for teaching health include a sound understanding of human biology, a knowledge of human anatomy and physiology, a knowledge of normal psychology and of social psychology, a knowledge of the agents that injure health and of defenses against them, a knowledge of the principles and practices of hygiene, a superior medical education or access to consultation with such a person and a knowledge of the technic of teaching.

Effective health teaching can arrive only when all our instructional influences integrate into a coordinate total health program, through the practice of individual hygiene, group hygiene and society hygiene. A knowledge of health does not produce health. Qualifications for teaching health are of the greatest importance for the teacher and for the individual being taught, but health comes not only from being taught and from the wisdom of understanding but from the favor of heritage and from the favor of environment and from the practice of behaviors that are favorable to health.

AUDIOMETERS AND THEIR PLACE IN THE SCHOOL PROGRAM

ISAAC H. JONES, M.D.
LOS ANGELES
AND
VERN O. KNUDSEN, PH.D.
LOS ANGELES

With money, and not an excessive amount, it would be a simple matter to have trained workers test the hearing of all school children, make a more careful examination of those who show a hearing defect and refer those who need treatment to their own physicians. If this were done hundreds of thousands of children would be saved from the handicap of becoming hard of hearing in later life. The universal experience of otolaryngologists has been that patients come to them too late. There is no approach to the prevention of deafness to compare with the systematic and universal exami-

nation of the hearing of school children. Last year in the state of California more than two million dollars was spent for the blind, one third furnished by the federal government, one third by the state of California and one third by the counties. Whether the money should come from this or other sources, the medical profession should bestir itself in this service but should make every effort to keep it free from unworthy political influence. Tests with the 4A audiometer by themselves do not meet the need but must be followed by individual audiometric tests and suitable treatment. Nine thousand students have been tested with audiometers annually in the Los Angeles public schools; there are two hundred thousand pupils

in the first eight grades. With a larger staff it would be possible to test twenty-five thousand pupils annually with one 4A audiometer. About half of the children are found to have an impairment of hearing of such a degree that they will require a careful routine ear, nose and throat examination. This would require two otolaryngologists, two nurses, two clinical audiometers, one 4A audiometer, two full time technicians and one full time clerk. Individual tests, to be accurate, must be conducted in a very quiet room or soundproof booth. After the audiometric and ear, nose and throat examination, notices should be sent to the parents recommending that they consult the ear, nose and throat specialist of their choice.

GRADUATE MEDICAL EDUCATION: TENNESSEE

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The Tennessee State Medical Association in 1936 formed a committee on medical education to study the educational needs of practicing physicians in the state. It was recommended by this committee that a postgraduate extension course in obstetrics be established, and the state association appropriated \$1,500 toward financing such instruction. Vanderbilt University, the University of Tennessee and the Tennessee Department of Public Health made similar or smaller contributions, the Commonwealth Fund of New York contributing a larger amount. A standing committee on postgraduate instruction in obstetrics was formed with four physicians from the association and one from each of the three contributing agencies in the state, with Dr. James R. Reinberger as chairman. An organization was created to provide for instruction with three full time employees, office space being donated by the University of Tennessee at Memphis. A trained and experienced field clinician, a field organizer and an office secretary inaugurated the proposed postgraduate course.

Instruction proceeded on the circuit plan, the state being divided into nine geographic divisions, excluding certain metropolitan sections until the rural areas had been covered. About ten counties constitute a circuit, and a two hour period of instruction is given weekly for ten times in each of the circuit's five or six teaching centers. An hour of lecture is followed by projection of movies or lantern slides and informal discussion and finally an examination of patients brought in by the local clinic chairman. Where clinical material is not available, manikins are used. Patients are seen in consultation without fee, this being considered a service of the state association. Lectures to the public are included, and in the first circuit seven lay groups were addressed by the field clinician, usually on antepartum care. Talks are given on request at regular meetings of county societies on subjects not included in the course.

A registration fee of \$5 was charged each physician. By March 1, 1938, 896 physicians of the 2,939 in the state had registered. There are 1,731 members of the state association. The average attendance has been approximately 87 per cent for the ten clinic periods. Certificates of attendance are being prepared for physicians who have attended seven or more of these meetings. An abstract of the lectures has been prepared by the field clinician and published by the committee to be supplied at the end of the course to all who have enrolled. More than half of the registrants have requested the postgraduate committee to furnish cards for making antepartum records. The first year's budget for the entire educational program was \$16,500. The course was publicized by the field organizer, who visited in person rural physicians in the area where the course was to be organized. These visits were followed by letters and cards announcing the course, and notices appeared in the state association's journal and in local newspapers.

Answers to a questionnaire submitted to physicians participating in postgraduate instruction indicate that courses are desired similar to the one being concluded this year in obstetrics. Pediatrics, internal medicine, surgical diagnosis, traumatic and orthopedic surgery and anatomy were the subjects most frequently requested by 275 of the 750 physicians ques-

tioned. It is hoped that physicians and agencies within the state may finance such instruction and provide for a permanent educational organization. Postgraduate teaching, as now being conducted, is believed to be an excellent means of reorganizing and reactivating dormant county societies for the primary purpose of elevating the standards of practice of rural physicians. At the same time the public is being educated to appreciate the advantages of proper medical care.

The Commonwealth Fund each year since 1930 has provided fellowships for twenty physicians of Tennessee seeking further training in medical centers. This year eight of the twenty registrants at Vanderbilt University School of Medicine will come from Oklahoma. Each applicant is interviewed personally and when accepted is given a stipend and traveling expenses. His tuition of \$150 and a small breakage fee are paid also. Four months of intramural instruction is given during the summer and is essentially the four year undergraduate course in miniature. Dr. John P. Youmans, director of postgraduate instruction, has divided the course into five periods. The first four weeks is devoted to clinical diagnosis and clinical laboratory methods and consists of essential practical work with patients, who are demonstrated in the outpatient clinics and hospital wards. Basic clinical sciences are reviewed also as they apply to the general practice of medicine. Four subsequent periods are devoted to a consideration of the broader aspects of medicine, surgery, pediatrics and obstetrics. There are from three to six members of the faculty teaching physicians in each division of medicine. Actual examination of patients, performance of laboratory procedures, ward rounds, conferences and informal lectures constitute the methods of instruction. Work in the specialties, including gynecology and preventive medicine and attendance at necropsies and clinical pathologic conferences, is afforded. Free use of the library is permitted. The emphasis is on learning by performance under close supervision. An appreciation by clinical instructors of the problems and limitations of general practice seems essential for the success of such an effort. Approximately 100 physicians have had the benefits of this training, although twice this number have applied.

The School of Medicine at Vanderbilt University also offers a three months postgraduate course in public health, for which the tuition is \$100. This course is designed primarily for health officers. Seventeen men from seven states are now registered. Physicians desiring special training in syphilology may join the staff of the University Clinic for varying periods, depending on the individual needs for training. Intensive intramural courses in other special subjects are offered during the summer. Daily practical and clinical instruction over two to three weeks is available in pediatrics, gynecology, obstetrics, x-ray, allergy, cardiovascular-renal diseases, diseases of the blood, metabolic and endocrine diseases and other special courses in the various divisions of medicine. Tuition fees from \$25 to \$100 are charged, the yearly registration averaging not more than five physicians.

The library at the School of Medicine at Vanderbilt University has a record of the number of loans made by physicians

in Tennessee over the past seven years. There were 145 journals or books lent to sixty-five individuals during this period.

The Department of Medicine of Meharry Medical College is offering a two weeks intensive review course this year in which the enrolment will be limited to from fifteen to twenty colored physicians. Subjects selected include physical diagnosis, clinical laboratory methods, syphilis, tuberculosis, cardiovascular-renal disease, gastro-enterology, urology, infectious diseases, cancer, pediatrics and obstetrics-gynecology. Ward rounds, attendance at clinics and clinical pathologic conferences and symposiums are to be stressed. A tuition fee of \$10 is to be charged.

The University of Tennessee College of Medicine offers graduate instruction in the department of orthopedic surgery leading to the degree of master of science in this subject. Five physicians have qualified for the course and are now engaged in a three year period of advanced study. Successful performance in preliminary and final oral, written and practical examinations and the preparation of an acceptable thesis are required. Similar courses in five other divisions of medicine are contemplated.

Of the several sectional medical societies in Tennessee, the Mid-South Postgraduate Medical Assembly is the oldest and best known. It was founded in 1883 as the Tri-State Medical Association and was reorganized in 1931 under its present name. It is the purpose of this group to provide instruction for physicians in the general vicinity of Memphis, where the four day meetings are always held. The present secretary-treasurer, Dr. A. F. Cooper, has organized and managed the assemblies during the sixteen year period he has held this office. This year's assembly was addressed exclusively by twenty-three out of state speakers. Many of the lectures were illustrated. There were round table discussions, symposiums and scientific exhibits. A \$5 registration fee is charged each registrant. This constitutes the dues, which, with the income from commercial exhibits, finance the activities of the assembly. The clinical reports are submitted to the *Mississippi Doctor* for publication. There were 1,252 who registered for the last assembly, 661 being physicians, 233 of whom were from Memphis, 115 from other parts of Tennessee and 131 from Mississippi, ninety-eight from Arkansas, sixteen from Alabama, fourteen from Missouri and ten or less from such states as Kentucky, Texas, Louisiana, Oklahoma, Kansas and Illinois. There were approximately 400 medical students and a number of nurses who attended. Each year there is an increased interest in this postgraduate assembly. Any physician in good standing in a state medical society may attend.

The Tennessee Valley Post Graduate Medical Assembly is organized exclusively for postgraduate study. The three day course of lectures by guest speakers provides physicians in the vicinity of Knoxville with a series of lectures and discussions on recent advances in medicine. Fifteen out of state speakers contributed to last year's program. Dr. Jesse C. Hill has been secretary of the assembly since it was founded four years ago. A \$4 registration fee is charged any physician affiliated with a state medical society who attends. Commercial exhibits aid in the financing. The attendance at these assemblies has averaged about 350, the physicians coming from Tennessee, Kentucky, Virginia, West Virginia, North Carolina and Georgia.

The Nashville Postgraduate Medical Association, of which Dr. Jefferson C. Pennington is secretary, was formed in 1934 to provide practicing physicians with an opportunity to examine, diagnose and treat patients in the wards and clinics of the Nashville General Hospital. The membership of the association has increased from fourteen to twenty-one, each member subscribing \$10. A two weeks period of lectures, demonstrations, medical, surgical, pediatric, obstetric, gynecologic and other specialty clinics and ward rounds are held each year. The attendance has varied from fifteen to thirty under the supervision of approximately sixty-five teachers, including members of the association. The attending physicians are divided into three groups to allow greater opportunity for learning and to provide more personal instruction, which is spread over a twelve hour period daily five days each week. Physicians who desire to see obstetric or other emergency cases at night may do so, and deliveries may be conducted under supervision. Physicians are circularized in middle Tennessee, southern Kentucky and northern Alabama, each registrant paying a fee of \$10.

The Middle Tennessee Medical Association, of which Dr. Daugh W. Smith is secretary-treasurer, was formed in 1887 to provide physicians in thirty-five counties of middle Tennessee with some annual postgraduate programs. Approximately 125 physicians attend yearly, each paying a \$3 registration fee. The last meeting, which was held in Dickson, was devoted to two days of lectures and discussions given by Tennessee physicians on thirteen subjects.

Three other district medical organizations give one or two day semi-annual or annual programs of lectures and discussions. These are the East Tennessee Medical Association, the West Tennessee Medical Association and the Upper Cumberland Medical Association. Guest speakers are invited. Registration fees are \$2, and the yearly attendance in each section is from 150 to 250 physicians.

The annual meeting of the Tennessee State Medical Association is devoted in part to graduate instruction. The approximate attendance each year is 700.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Personal.—Dr. William M. Bevis, clinical director of Soldiers Home Hospital, Mountain Home, Tenn., has been appointed to a similar position at the Veterans' Administration Facility, Whipple.

ARKANSAS

District Meetings.—The Ninth Councilor District Medical Society was addressed in Harrison June 7 by Drs. Seldon W. Chambers, Harrison, on "Activities of the Full Time County Health Officer and His Relations with the Family Physician"; Davis W. Goldstein, Fort Smith, "Control of Syphilis"; Ross E. Fowler, Harrison, "Preoperative Treatment of Prostatic Obstruction," and Henry V. Kirby, Harrison, tularemia. At a meeting of the Fifth Councilor District Medical Society in Magnolia June 14 the speakers were Drs. George H. Robinson, Shreveport, "Conservative Treatment of the Ruptured Appendix"; Ralph Bowen, Oklahoma City, allergy, and Henry King Wade, Hot Springs National Park, diseases of the testicles.

CALIFORNIA

Changes in Health Officers.—Dr. Paul W. Schriber has been appointed health officer of Atwater, succeeding Dr. Clarence C. Fitzgibbon, Merced. Dr. Fitzgibbon is health officer of Merced County.—Dr. Burton L. Zinnamon, San Francisco, has been appointed health officer of Sonoma County, effective July 1; the unit was recently placed on a full time basis. Dr. Frank E. Sohler Jr. has succeeded Dr. Donovan C. Oakleaf as health officer of Cloverdale.—Dr. Francis J. Peter has been appointed health officer of Turlock, succeeding Dr. Charles E. Pearson.

Society News.—Dr. Leo Eloesser, recently returned after spending nine months with the government forces in Spain, will address a special meeting of the San Francisco County Medical Society August 23 on "War Surgery in Spain." Dr. Philip E. C. Manson-Bahr, London, England, will address a general meeting of the society August 30 on "Differential Diagnosis of Fever from a Practical Point of View."—Dr. Harry Clare Sheppardson, San Francisco, discussed "Clinical Experiences with Long-Acting Insulins" before the Hollywood Academy of Medicine July 14.

FLORIDA

Personal.—Dr. Lauren McCall Sompayrac, Jacksonville, was awarded the Robert L. Schirmer cup July 12 by the Junior Chamber of Commerce, in recognition of his "meritorious leadership" during the past six months. Dr. Sompayrac has been chairman of the health and sanitation committee, which is actively engaged in a campaign against venereal diseases; he is also president of the Duval County Social Hygiene Council.

Society News.—Dr. Julian Deryl Hart, Durham, N. C., discussed the use of ultraviolet rays in sterilizing the operating room before the Hillsborough County Medical Society June 7.

—Officers of the Florida Radiological Society elected at its recent annual meeting are Drs. Harold O. Brown, Tampa, president; Harry B. McEuen, Jacksonville, vice president, and Joseph H. Lucinian, Miami, secretary.—Dr. Arthur J. Bieker discussed "Cardiology in Aviation" before the Pinellas County Medical Society in St. Petersburg July 1.

District Meeting.—The Northeast Medical District Society will hold its second annual meeting in Ponte Vedra September 15 at the Old Club, under the presidency of Dr. Wilfred McL. Shaw, Jacksonville. Dr. James Lunsford Boone, Jacksonville, president, Duval County Medical Society, will give the address of welcome. In addition to speeches by some of the officers of the state medical society, addresses will be delivered by the following:

Dr. Charles E. Tribble, DeLand, Dystocia Due to Sacral Teratoma.
Dr. Allen P. Gurganious, Palatka, Common Sense Medicine.
Dr. Evan B. Wood, Daytona, Coronary Occlusion.
Dr. Vernon A. Lockwood, St. Augustine, Industrial Disability—Its Evaluation and Prevention.

GEORGIA

New Director of Cancer Division.—Dr. Ralph Mosteller, pathologist and director of the laboratory, Spartanburg General Hospital, Spartanburg, S. C., has been appointed director of the division of cancer control of the state department of health, Atlanta, it is reported. He succeeds Mr. J. W. Scherschewsky. Dr. Mosteller graduated at the University of Georgia School of Medicine, Augusta, in 1931.

IDAHO

State Medical Meeting at Sun Valley.—The Idaho State Medical Association will hold its annual meeting at the Challenger Inn, Sun Valley, September 6-10, under the presidency of Dr. Arthur C. Jones, Boise. The program is a graduate course of lectures in the morning and afternoon and round table conferences at luncheon. Members of the faculty of the University of Michigan Medical School, Ann Arbor, will be the lecturers this year:

Howard B. Lewis, Ph.D., Use and Abuse of the Methods of Blood Chemistry.
Dr. Cyrus C. Sturgis, Recent Advances in the Treatment of Blood Diseases.
Dr. Frederick A. Collier, Fluid and Electrolyte Balance in the Sick Patient.
Dr. Norman F. Miller, Obstetric Forceps—Their Use and Misuse.
Dr. Albert C. Furstenberg, The Clinical and Pathologic Study of Tumors and Cysts of the Head and Neck.

The speakers will deliver other lectures during the five day session.

ILLINOIS

Society News.—Dr. Lewis C. Scheffey, Philadelphia, addressed a meeting and conducted a clinic at the Sloan Clinic, Bloomington, June 22-23; his subject was "Changing Concepts in the Management of Cancer of the Body of the Uterus."—Dr. Joseph J. Link, Mattoon, discussed preoperative and post-operative care at a meeting of the Coles-Cumberland County Medical Society in Charleston July 13.—Dr. Carlo S. Scuderi, Chicago, addressed the Marion County Medical Society July 28 on "Modern Concept of Fractures of the Neck of the Femur."

Chicago

Dr. De Lee Honored.—The main building of the Chicago Lying-In Hospital group on the Midway will in the future be known as the Joseph B. De Lee Hospital in honor of its founder, in accordance with a recent change in contract merging the hospital with the University of Chicago. Since the merger with the university, the name of the hospital has become "The Chicago Lying-In Hospital of the University of Chicago." In addition to the main section of the building, named in honor of Dr. De Lee, there is the "Mothers' Aid Pavilion" for isolation cases and the "Max Epstein Clinic," the outpatient division. The university agreed in the contract to continue the operation of the Stock Yards Dispensary, 734 West Forty-Seventh Street, which was operated by the hospital, for five years and thereafter as long as it may be useful. The service to women is also to be continued. Property heretofore used for the work of the Chicago Maternity Center has been given to that organization by the hospital. Dr. De Lee founded the Chicago Lying-In Hospital in a tenement house in Maxwell Street in 1895. He is professor emeritus of obstetrics and gynecology at the university.

Annual Occupational Disease Symposium.—The department of industrial medicine of Northwestern University Medical School will conduct its second annual symposium on occu-

pational disease at Thorne Hall on the Chicago campus September 26-27. The speakers will include:

Dr. Carl M. Peterson, Secretary, Council on Industrial Health, American Medical Association, Industrial Disease Education.
Philip Drinker, Ch.E., professor of industrial hygiene, Harvard School of Public Health, Boston, The Scope of the Occupational Disease Research Problem.
Dr. Lewis J. Pollock, professor of nervous and mental diseases at Northwestern, Traumatic Neurosis.
Mr. Arthur H. Young, industrial relations counselor, The Place of Medical Service in Industrial Relations.
Dr. John G. Cunningham, Toronto, Canada, Industrial Plant Surveys.
Dr. Stanley J. Seeger, Milwaukee, chairman, Council on Industrial Health, American Medical Association, Industrial Health and Safety and the Practicing Physician.
Dr. Edgar V. Allen, Rochester, Minn.
Dr. James G. Carr, secretary and professor of medicine at Northwestern.

Dr. Irving S. Cutter, dean of the medical school, will be toastmaster at the banquet at the Blackstone Hotel in the evening and Mr. O. E. Mount, American Steel Foundries, will speak on "Industrial Health—The Responsibility of Labor, Management and the Community."

INDIANA

Personal.—Dr. Fletcher C. Stewart, Fort Stanton, N. M., has been appointed medical officer in charge of the U. S. Marine Hospital, Evansville.—Dr. Wallace E. Childs, Madison, was appointed, July 1, director of district health unit number one, consisting of Gibson, Pike, Posey and Warrick counties.

LOUISIANA

Society News.—At the joint scientific and executive meeting of the Orleans Parish Medical Society, New Orleans, July 11 the speakers were Drs. Narcisse F. Thiberge on "Study of the Thrombocyte in Allergy" and Merrill C. Beck, "Cyclopropane—Advantages and Disadvantages."—A recent meeting of the Morehouse Parish Medical Society was addressed in Bastrop by Dr. Charles J. Raney, Bastrop, on undulant fever.

New Director of Venereal Disease Control.—Dr. Ford S. Williams, director of the St. Mary Parish Health Department, Franklin, has been appointed state director of venereal disease control by the state board of health. Dr. Williams graduated at the Louisiana State University Medical Center, New Orleans, in 1934. He will be succeeded as director of the parish unit by Dr. Paul S. Parrino.

MASSACHUSETTS

Personal.—Dr. Malcolm J. Farrell, Waltham, has been appointed assistant superintendent of the Walter E. Fernald State School, Waverley, succeeding Dr. Charles S. Woodall, who resigned to become superintendent of the Brandon State School, Brandon, Vt.

State Medical Election.—Dr. Channing Frothingham, Boston, was elected president of the Massachusetts Medical Society at its annual meeting in Boston June 1. Dr. Albert W. Stearns, Billerica, was chosen vice president and Dr. Alexander S. Begg, Boston, reelected secretary.

MICHIGAN

Outbreak of Dysentery—Six Deaths.—The deaths of six children were reported in an outbreak of dysentery in Owosso, according to the Chicago Tribune August 7. Eight patients were ill in the hospital. Preliminary investigation revealed the disease to be Shiga dysentery, it was stated, and the state department of health had set up a laboratory in the town to study the outbreak.

Changes in Health Officers.—Dr. Ragnar T. Westman, Bay City, has resigned as director of the health department of Bay County. Dr. James A. Dolce, Charlotte, has been appointed assistant director and county health officer of Allegan County, it is reported. Dr. Morley B. Beckett, who recently resigned as county health officer, will continue as director of the Allegan and Van Buren county units, it was stated. Dr. Clifton C. E. Merritt, Iron Mountain, has resigned as health officer of Dickinson County to succeed Dr. Westman in Bay County.

MINNESOTA

Personal.—Dr. Abel R. Ellingson, Detroit Lakes, has been elected coroner of Becker County.—A testimonial dinner was held in honor of Dr. and Mrs. Aaron E. Henslin, LeRoy, in recognition of the completion by the former of forty-three years in the practice of medicine.

Commonwealth Fund Aids Graduate Teaching.—The courses offered to practicing physicians during the past two years by the Post Graduate Medical Institute in connection with

the Center for Continuation Study, University of Minnesota, have proved so popular that the Commonwealth Fund of New York is subsidizing the further development of the program over the next five years. Dr. William A. O'Brien, associate professor of preventive medicine and public health at the medical school, has been relieved of other duties to become director of postgraduate medical education on a full time basis. The Center for Continuation Study was erected late in 1936 at a cost of \$300,000. It is used jointly by the professional schools of the University of Minnesota for intensive resident graduate instruction and contains living rooms for seventy-eight graduate students, dining hall, lounge, library, chapel, classrooms, administrative offices and parking garage. Any physician who is a member of his local medical society may attend the courses.

MONTANA

Plague Infection.—Plague infection has been proved in pooled tissue from two ground squirrels, and in a pool of ninety-eight fleas from twenty-eight ground squirrels of the same species, all taken June 24 ten miles north of Wisdom on Plempton Creek, Beaverhead County.

NEBRASKA

Graduate Course in Omaha.—The state department of health and the maternal and child health committee of the Nebraska State Medical Association sponsored a graduate course in obstetrics, gynecology and pediatrics July 11-23, given by members of the faculties of Creighton University and the University of Nebraska schools of medicine, Omaha. Clinics and demonstrations were held at St. Joseph's and University hospitals as well as at the universities.

NEW YORK

School Physicians' Meeting.—Dr. Michael Levitan, Rome, was elected president of the New York State Association of School Physicians at the annual meeting in Saratoga Springs June 27; Dr. Louis A. Van Kleeck, Manhasset, vice president, and Dr. Clara Adele Brown, Oswego, secretary. Among the speakers at the meeting were Drs. Alfred W. Jacobsen, Buffalo, on "Endocrine Studies in School Children"; Ernest L. Stebbins, Albany, "Communicable Diseases and the School," and John E. Burke, Schenectady, "Attacking Mental Hygiene Problems in the School."

Personal.—Dr. Arnold Shamaskin has resigned as medical superintendent of the Montefiore Hospital Country Sanatorium, Bedford Hills, to become superintendent and medical director of the Jewish Consumptives Relief Society Sanatorium in Spivak, Colo., October 1.—Dr. Benjamin White Seaman, Hempstead, was the first person to receive an annual award established recently by the Nassau Daily Review-Star for the "most valuable service to the whole community by a local resident." The award, a medallion and citation, was presented at a dinner June 27, attended by 450 citizens of Nassau County. Arthur T. Vanderbilt, Newark, N. J., president of the American Bar Association, was the principal speaker. Dr. Seaman was honored for his activities in connection with the establishment of the Meadowbrook Hospital, Hempstead, completed in 1937.

New York City

Personal.—Dr. Francis Peyton Rous of the Rockefeller Institute for Medical Research received the honorary degree of doctor of science from the University of Cambridge, England, June 10. Dr. James B. Murphy of the institute received the honorary degree of doctor of science from Oglethorpe University, Atlanta, recently.—Dr. J. Bentley Squier was decorated by Crown Prince Gustaf Adolf of Sweden during his recent stay in the United States; Dr. Squier was made a Commander of the Order of the North Star.—Dr. Anthony Bassler received the honorary degree of doctor of laws from Hahnemann Medical College of Philadelphia June 9.

Society News.—Dr. Nathaniel E. Selby addressed the Bronx County Medical Society June 15 on "Hypnotism—Its Scientific Basis and Medical Application."—The Society for the Aid of Crippled Children in Palestine has recently formed a medical unit in New York. Dr. Michael S. Burman is chairman; Dr. Samuel E. Sinberg, vice president, and Dr. H. Howard Green, secretary. Dr. Henry Keller is surgical director of the society.—The Medical Society of the County of Queens will be addressed September 27 by Drs. Foster Kennedy on "The Organic Background of Mind" and Elizabeth I. Adamson, "Mild Depressions Cared for by Family Doctor."

Proposed City Food and Drug Bill.—A bill requiring registration of proprietary foods and drugs has been introduced in the city council and will probably be brought up for action in September. The bill requires payment of an initial registration fee of \$25 for every proprietary product with subsequent annual fees of \$10. Manufacturers would have to provide a statement of formula, qualitative and quantitative, and a list of judgments or decrees against the product by courts or government agencies; drug manufacturers would have to state the therapeutic or cosmetic value of their products and standards would have to be adopted, according to *Advertising Age*. A protest has been lodged with Mayor La Guardia by the Toilet Goods Association.

NORTH DAKOTA

Personal.—Dr. Elizabeth C. Smith, formerly of the division of maternal and child health of the Pennsylvania state department of health, has joined the staff of the division of child hygiene of the North Dakota State Department of Health.

State Medical Election.—Dr. Harry A. Brandes, Bismarck, was chosen president-elect of the North Dakota State Medical Association at the recent annual meeting in Bismarck. Dr. William H. Long, Fargo, will be the president for the coming year. Vice presidents elected were Drs. Cyril J. Glaspel, Grafton, and Frederick W. Fergusson, Kulm. Dr. William W. Wood, Jamestown, was elected secretary, and Fargo was chosen as the place for the 1939 meeting.

OHIO

University News.—Two gifts totaling \$19,000 were given to the University of Cincinnati College of Medicine, Cincinnati, for research. One of \$14,000 was given by the John and Mary R. Markle Foundation, New York, for a two year period to aid Dr. Tom D. Spies, associate professor of medicine, in his work on pellagra. The Taylor Instrument Companies, Rochester, N. Y., contributed \$5,000 for further investigations in the field of vascular problems.

PENNSYLVANIA

Society News.—Dr. Joseph H. Barach, Pittsburgh, addressed the Indiana County Medical Society, Indiana, June 9, on "Present Day Conceptions and Treatment of Diabetes." Dr. Barach addressed the Crawford County Medical Society, Titusville, June 22, on "Clinical Interpretation of Arterial Hypertension and Arterial Hypotension."

SOUTH CAROLINA

Personal.—Mr. James L. Rogers, business manager of the Spartanburg General Hospital, Spartanburg, has been named superintendent of the hospital, effective July 15, following the resignation of Dr. James Moss Beeler to accept a similar position at the Grady Hospital, Atlanta, Ga.—Drs. Josiah S. Matthews, Denmark, and George R. Wilkinson, Greenville, were recently reappointed to the state board of medical examiners for terms of four years.—Dr. James L. Mims, Chester, has been appointed health officer for Jasper County, succeeding Dr. John B. Wallace, Fountain Inn, who returned to private practice.—Dr. Richard K. Brown of the staff of the Georgia State Tuberculosis Sanatorium, Alto, Ga., has been appointed superintendent of the Greenville County Tuberculosis Hospital, Greenville.—Dr. Thomas K. Fairey, Johnston, has been appointed health officer of Union County.—Dr. Richard M. Street, Laurens, recently resigned as health officer of Abbeville and Laurens counties.

Society News.—At a meeting of the Second District Medical Association at Aiken July 28 the speakers were Drs. Richard Torpin, Augusta, Ga., on "Ectopic Pregnancy, Diagnosis and Treatment"; Julian D. Hart, Durham, N. C., "Sterilization of Air in Operating Rooms," and Alfred F. Burnside, Columbia, "Varicosities of the Lower Extremities." Dr. Douglas Jennings, Bennettsville, president-elect of the South Carolina Medical Association, made an address.—The Lee County Medical Society was recently reorganized with the following officers: Drs. John B. Cousar, Bishopville, president; Robert O. McCutchen, Bishopville, vice president, and Donald E. Michie, Bishopville, secretary-treasurer. Speakers at the reorganization meeting were Drs. James R. Des Portes, Fort Mill, president of the South Carolina Medical Association; Edgar A. Hines, Seneca, secretary of the association, and Edward T. Kelley, Kingstree, councilor of the seventh district.—At a meeting of the Columbia Medical Society July 11 the speakers included Drs. Coyt Ham, Sol B. McLendon and Glenn B. Carrigan, Columbia, on treatment of dementia praecox with

insulin and metrazol.—Dr. Elija M. Hicks, Florence, read a "Review of the Pituitary and Ovarian Hormones" before the Florence County Medical Society recently.

UTAH

State Medical Meeting at Ogden.—The forty-fourth annual meeting of the Utah State Medical Association will be held in the new High School Building, Ogden, September 1-3, under the presidency of Dr. Menzies J. Macfarlane, Cedar City. Included on the program will be the following:

- Dr. Owen H. Wangenstein, Minneapolis, Role of the Surgeon in the Treatment of Pyogenic Infections.
- Dr. Alvin G. Foord, Pasadena, Calif., Pathology of Tumor Nodules in the Breast.
- Dr. Roger Anderson, Seattle, Fractures of the Shaft of the Femur.
- Dr. Harry H. Bowing, Rochester, Minn., Advancements Made in the Treatment of Carcinoma of the Rectum.
- Dr. Edmund W. Butler, San Francisco, Acute Traumatic Injuries of the Chest.
- Dr. Milton J. Rosenau, Chapel Hill, N. C., Pneumonia: Epidemiology, Treatment and Prevention.
- Dr. Jacob Arnold Bergen, Rochester, Minn., Diverticulosis and Diverticulitis of the Large Intestine.
- Dr. Irvine McQuarrie, Minneapolis, Pathogenesis and Treatment of Edema in Children.
- Dr. Nathaniel G. Alcock, Iowa City, Treatment of Enlarged Prostate.
- Dr. Arnold S. Jackson, Madison, Wis., Gallbladder Operations.
- Dr. William J. Kerr, San Francisco, Angina Pectoris, New Concepts of Etiology and Treatment.
- Dr. Howard C. Naffziger, San Francisco, Peripheral Nerve Injuries and Their Treatment.
- Dr. Irvin Abell, Louisville, Ky., President of the American Medical Association, Correction of Retrodisplacements and Complete Prolapse of the Uterus.

Dr. Rosenau will address a public meeting Thursday evening on "Fads and Fancies in Preventive Medicine and Public Health" and the annual banquet Friday evening on "Serendipity."

VIRGINIA

Director of State Hospitals Appointed.—A central office for supervision of the state hospitals and the Colony for the Epileptic and Feeble-minded has recently been established in Richmond with Dr. Hugh C. Henry, Petersburg, as director. Dr. Henry, a graduate of the Medical College of Virginia in 1896, has been superintendent of the Central State Hospital at Petersburg since 1924.

WASHINGTON

Courses in Obstetrics.—Dr. Everett D. Plass, professor of obstetrics and gynecology, State University of Iowa College of Medicine, Iowa City, recently gave a group of lectures on obstetrics in Yakima, Walla Walla, Spokane, Bellingham, Tacoma, Chehalis and Seattle. The short courses continued for three days each.

State Medical Meeting at Bellingham.—The Washington State Medical Association will hold its annual meeting at the Bellingham Hotel, Bellingham, August 29-31, under the presidency of Dr. J. Reid Morrison, Bellingham. The speakers will include:

- Dr. Byron F. Francis, Seattle, Recent Advances in Our Knowledge of Pulmonary Emphysema.
- Dr. Edwin E. Osgood, Portland, Principles Which Should Govern the Therapeutic Use of Sulfanilamide.
- Dr. Don C. Sutton, Chicago, Prophylaxis of Age.
- Dr. Edward C. Moore, Los Angeles, Surgical Analysis of Biliary Surgery with Technic for Cholecystectomy.
- Dr. Frederick Lemere, Seattle, Treatment of Mild Depression, A Common Neuropsychiatric Disorder Frequently Seen by the General Practitioner.
- Dr. David Metheny, Seattle, Nutritional Deficiencies Complicating Surgery of the Gastrointestinal Tract.
- Dr. Ralph H. Loe, Seattle, Gastroscopy.

The Public Health League of Washington and the Washington State Medical Service Bureau will hold their annual meetings during the session. The woman's auxiliary to the state society will also meet.

WISCONSIN

Society News.—Drs. Paul Padgett, Baltimore, and Harold W. Shutter, Milwaukee, addressed the Columbia-Marquette-Adams County Medical Society, Wisconsin Dells, recently on "Care and Treatment of Syphilis" and "Toxemias of Pregnancy" respectively.—Dr. William T. Lindsay, Madison, addressed the Dodge County Medical Society, Beaver Dam, recently, on the disease of the pancreas.—At a meeting of the Kenosha County Medical Society in Kenosha in May Dr. George F. O'Brien, Chicago, spoke on coronary diseases.—Dr. James A. Evans, La Crosse, discussed "Lesions of the Gastro-Intestinal Tract" before the Monroe County Medical Society, Sparta, recently.—At a meeting of the Pierce-St. Croix County Medical Society, Ellsworth, recently, Dr. Willis H. Thompson, Minneapolis, presented papers on "The Use of

Sulfanilamide in the Treatment of Diseases of Children" and "The Immunization of Children Against Whooping Cough, Diphtheria and Smallpox."—Drs. George W. Stuppy and Willard L. Wood, Chicago, addressed the Rock County Medical Society, Janesville, June 28, on "The Application of Allergy to Internal Medicine."—Dr. Cornelius H. Cremer, Cashton, was recently elected president of the state board of medical examiners.

PHILIPPINE ISLANDS

First Preventorium Opened.—The Quezon Preventorium of the White Cross, first tuberculosis preventorium in the Philippines, was opened in April in San Juan. Dr. Isidro Pertierra is director of the new institution, which has a capacity of 300 beds.

GENERAL

Examinations in Internal Medicine.—Written examinations for certification by the American Board of Internal Medicine will be held in various parts of the United States Monday October 17 and Monday Feb. 20, 1939. Formal application must be received by the secretary, Dr. William S. Middleton, 1301 University Avenue, Madison, Wis., before September 15 for the October examination and before January 1 for the February 1939 examination.

American Social Hygiene Association.—The American Society for the Control of Venereal Diseases, Inc., organized in California in 1937, has merged with the American Social Hygiene Association and will function as the Western division of the association, with headquarters at 45 Second Street, San Francisco. The Western division will be under the direction of a Western advisory committee including Drs. Ray Lyman Wilbur, Russell V. Lee, Stanford University, Calif.; Thomas A. Storey, William P. Shepard and Mr. Ray W. Smith, San Francisco.

Study of Tuberculosis in Newfoundland.—The International Grenfell Association is conducting a survey of the incidence of tuberculosis in northern Newfoundland. The survey was begun July 1 under the direction of Drs. Charles S. Curtis, medical superintendent of the Grenfell Hospitals in Newfoundland and Labrador, and Theodore L. Badger, Boston, president of the New England Grenfell Association, with the assistance of Dr. Roy M. Seideman, New York. They plan to make a tuberculin study in all age groups with x-ray examinations and studies of family contacts.

New Journal of Neurology.—*Confinia Neurologica* is a new journal to be published every two months with the object of "maintaining the mutual relationship of neurology and surgery, oto-ophthalmology, syphilology, endocrinology and radiology." Original articles, reviews, society transactions and book reviews are to be published. The articles may appear in English, French or German; original papers will have summaries in all three languages. Manuscripts, books for review and other communications should be sent to the editor, Dr. Ernest A. Spiegel, professor of experimental and applied neurology, Temple University, Broad Street at Ontario, Philadelphia.

Reunion of Veteran Medical Corps.—The medical corps of the various branches of government service are planning a reunion in Los Angeles, September 19-22, in conjunction with the national American Legion convention. Dr. Charles W. Decker has been appointed chairman of the medical corps reunion committee, which has established headquarters at the Ambassador Hotel, 3400 Wilshire Boulevard, Los Angeles. Members of the army, navy, air service and the marine and dental corps are invited to take part in the reunion, which marks the twentieth anniversary of the end of the World War. A luncheon at the Coconut Grove of the Ambassador Wednesday, September 21, will be one feature of the reunion.

Rural Health Awards.—Winners in the recent rural health conservation contest conducted by the U. S. Chamber of Commerce in cooperation with the American Public Health Association were as follows:

- Northeastern division: Columbia County, N. Y.
- Eastern division: Fayette County, Ky.
- Southeastern division: Pike County, Miss.
- North central division: Woodbury County, Iowa.
- South central division: Amarillo and Potter County, Texas.
- Western division: Clallam County, Wash.

Special awards were presented to Davidson County, Tenn.; El Paso, Texas, and Shawnee County, Kan., for having won the rural health contest twice and for having maintained their previous high standards of achievement during 1937. The rural health contest was financed by the W. K. Kellogg Foundation of Battle Creek, Mich.

Dr. Heiser to Direct Study of Healthful Working Conditions.—The National Association of Manufacturers has organized a committee on healthful working conditions and has appointed Dr. Victor G. Heiser, New York, internationally known hygienist for many years with the Rockefeller Foundation, as research director. A survey of plant conditions will be undertaken immediately and an information service will be established for approximately 80,000 factories employing from twenty-five to 2,000 workers. The committee was created recently with a view to assisting American industry in the field of industrial health and with the hope of bringing about a wider extension of medical service for workers. Dr. Donald M. Shafer, formerly of St. George, Staten Island, N. Y., was appointed assistant to Dr. Heiser. Headquarters of the committee are at 14 West Forty-Ninth Street, New York.

Aero Medical Association.—The tenth annual meeting of the Aero Medical Association of the United States will be held at Dayton, Ohio, September 2-4, with headquarters at the Biltmore Hotel. Some sessions will be held at Patterson and Wright fields. According to the tentative program, the following will speak, among others:

- Capt. Charles T. Leatham, medical corps, U. S. Army, director, department of aviation medicine, Randolph Field, Tex.
 Flying—A Discussion of the Use of the Electrocardiograph in the Flying Examinations. Its Possibilities and Limitations.
 Capt. Harry G. Armstrong, medical corps, U. S. Army, and John W. Heim, Ph.D., Boston, physiologic research laboratory, Wright Field, Effect of Acceleration on the Living Organisms.
 Dr. Ralph N. Greene, Coral Gables, Eastern Airlines, Air Transport Flying from . . .
 Dr. Eldridge S. Adams, Washington, section, bureau of air commerce, U. S. Department of Commerce, Problems Pertaining to the Department.

Society of American Bacteriologists.—The fortieth annual meeting of the Society of American Bacteriologists will be held at the Hotel Fairmont, San Francisco, August 30-September 1. Sections have been designated immunity, nitrogen fixation, pathogenic organisms, milk, water, food, methods, germicides, filtrable viruses, yeasts, fermentations and soil. A joint meeting of all sections Wednesday will be devoted to a consideration of enzymes in relation to bacteriology. Speakers will include:

- Dr. Monroe D. Eaton Jr., New York, The Soluble Malarial Antigen in the Serum of Monkeys Infected with Plasmodium Knowlesi.
 Dr. Stuart Mudd, Philadelphia, Certain Newer Aspects of the Antigenic Composition of Hemolytic Streptococci.
 Dr. George E. Rockwell, Cincinnati, An Experimental Study of the Treatment of Pneumococcal Toxemia with a Special Carbon Preparation.
 René J. Dubos, Ph.D., New York, Immunization of Experimental Animals with a Soluble Antigen Extracted from Avirulent Pneumococci.
 Benjamin S. Levine, Ph.D., Washington, D. C., Experimental Staphylococemia in White Mice Produced by the Intraperitoneal Injection of Mucin-Suspended Staphylococci.

Police Seek Wounded Man.—Physicians are asked to watch for a man named Huron Ted Walters, who may attempt to secure surgical treatment for a gunshot wound about eight inches above the knee. The wounded man is known to be traveling with one Floyd Garland Hamilton, although, in the one instance in which the Federal Bureau of Investigation was told that a doctor was visited, Walters entered the office alone. The men are reported to be in Illinois. Walters is 25 years of age. His description reads: height, 5 feet 8 inches; weight, about 145 pounds; eyes, gray-brown; hair, chestnut; complexion, medium dark; build, medium; race, white; nationality, American; education, grammar school. Hamilton is 30 years of age. His identification is as follows: height, 5 feet 10 inches; weight, 155; eyes, blue; hair, light brown; complexion, medium, sallow; build, slender; race, white; nationality, American. Both men are said to have had grade school education. Physicians visited by either of these men are asked to notify D. M. Ladd, special agent in charge, at Randolph 6226, or room 1900, 105 West Adams Street, Chicago.

FOREIGN

Personal.—Dr. James D. Boyd, lecturer in anatomy, University of Cambridge, has been appointed to the chair of anatomy at London Hospital Medical College, according to *Science*.

Society News.—The Association for Photographic and Cinematographic Documentation in the Sciences will hold its annual meeting in Paris October 6-7. All material sent from abroad must be addressed the Musée Pédagogique de l'Etat, 29 rue d'Ulm, Paris (5), Congrès de Documentation Photographique et Cinématographique. The closing date is October 1.

Congress of Comparative Pathology.—The fourth International Congress of Comparative Pathology will be held in Rome May 15-20, 1939, under the presidency of Prof. Pietro Rondoni, director of the cancer institute and of the Institute of General Pathology of the Royal University of Milan. The secretary is Prof. Vittorio Zavagli, director of the experimental station for animals, Rome, and the general secretary is Dr. Ugo Frasccherelli, secretary of the National Research Council, Piazzale delle Scienze, Rome. Meetings will be held at the Royal University of Rome and the Institute for Public Health. There will be three sections: human medicine, veterinary medicine and phytopathology. Subjects to be discussed include ultravirus diseases, heredity in pathology, function of the associated antigens and regressive processes in plants.

CORRECTION

Infantile Cerebral Palsy.—Dr. Clarence H. Heyman writes that the sentence in the summary of his article in *THE JOURNAL*, August 6, page 493, which reads "Asymmetrical lesions indicate some factor operating before birth," should read "Asymmetrical lesions indicate a likely traumatic origin during birth, while the symmetrical lesions indicate some factor operating before birth."

Government Services

Physician to Advise on Food, Drug and Cosmetic Advertising

Dr. Knox E. Miller, surgeon, U. S. Public Health Service, has been assigned to act as technical consultant to the Federal Trade Commission, passing on medical and other claims made in advertising of food, drug and cosmetic products under the Wheeler-Lea act. Dr. Miller will arrange for such other assistance as may be necessary, "particularly in the line of laboratory examinations." Cooperation with existing federal laboratories is to be continued.

Examination for Assistant Physician at St. Elizabeths

The U. S. Civil Service Commission announces an open competitive examination for first assistant physician (psychiatrist) to act as assistant superintendent of St. Elizabeths Hospital, Washington, D. C. Applications must be on file with the commission by September 6. If received from the following states, they may be received by September 9: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming. The salary is \$6,500 a year, with a deduction of 3.5 per cent toward a retirement annuity and a further deduction of \$300 for quarters and subsistence. The duties of the position are "to act as assistant superintendent of the hospital; to exercise general supervision over the medical, scientific and allied professional activities and carry into effect the policies of the superintendent in the care and treatment of patients; and upon authority of the superintendent to plan and initiate, supervise, evaluate and be responsible for the administrative proceedings of the hospital, professional care of the patients and research problems. Competitors will not be required to report for examination at any place but will be rated on the extent of their education and experience. Applicants must have been graduated from a recognized medical school, except that the standing of the medical school may be waived in the case of graduates otherwise qualified who have had one year of satisfactory service in the commissioned medical corps of the Army, Navy or U. S. Public Health Service. They must have had at least ten years of experience in the care of patients with mental disease, five of which must have been in a senior administrative capacity. At least five years of experience must have been acquired within the ten year period immediately preceding the closing date for receipt of applications. Applicants must not have passed their fifty-third birthday, except in the case of persons granted preference because of military or naval service. Further details are given in the application form, which may be obtained from the secretary, board of civil service examiners at any first class postoffice, from the commission at Washington, D. C., or from the district offices of the commission at any of the following cities: Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St. Louis, St. Paul, San Francisco, Honolulu, Balboa Heights, Canal Zone, and San Juan, P. R.

Foreign Letters

The Induction of Abortion in a Case of Rape

To the great satisfaction of the medical profession, Mr. Aleck Bourne, who was prosecuted for curetting a girl aged 14, who had become pregnant after rape, has been acquitted. The attorney general, who prosecuted, admitted that if the operation was done to save the mother's life it would not be unlawful, but he contended that the law meant immediate danger to life, not danger to health. In his evidence Mr. Bourne stated that in 1935 he did a similar operation on a girl of 15 and his house surgeon declined to assist him on religious grounds. This refusal led Mr. Bourne to decide that on the next occasion he would obtain the ruling of the court. If there were adequate medical reasons in the widest sense, on his interpretation of the law, based on the everyday practice of reputable members of the profession, he considered it justifiable to terminate pregnancy, and he could not draw a line between danger to life and danger to health. If a doctor waited for danger to life, the woman was past assistance. He emphatically included the preservation of mental health and the health of the nervous system among his indications. He did not think that the physical injuries in the present case would have caused difficulty of delivery, but the circumstances were such as to implant seeds of terror in the girl's mind. Fear and terror were the most serious deterrents to the unfolding of the whole process, so that assistance might be needed. The fact that the girl was a virgin who had been raped was a strong element in making up his mind. Her age was another; the chief bones of the pelvis were not united. Dr. J. R. Rees, medical psychologist, and Mr. William Gilliatt, obstetric surgeon, gave evidence in support of Mr. Bourne's view. Lord Horder said that he was not infrequently consulted in cases in which a severe mental or nervous breakdown seemed likely to occur if pregnancy was not terminated. The operation was justifiable in such cases. The facts of the child's age and the rape would have led him to the same conclusion.

The attorney general suggested that there was a fundamental difference between preserving life and preserving health. He also argued that the operation had not been done only for the purpose of preserving life. Mr. Bourne had never contended that the operation was necessary to preserve the immediate life of the girl. The judge said that as far as he knew a case of this type had never come before a jury in such circumstances. Even among counsel there seemed to have been some doubt about the expression of the law. The case was of great importance to the medical profession. It had nothing to do with the ordinary case of procuring abortion. The judge could not agree with the attorney general that there was a clear dividing line between danger to life and danger to health. Impairment of health might reach a stage where it was a danger to life. If the jury could not say that there was this division into two separate classes, they might, as put forward by the defense, consider the words "for the purpose of preserving the life of the mother" in a wide and liberal sense. In the medical profession there was a great divergence of view. Some persons held that the desire of the woman for the operation was sufficient justification. That was not the law. On the other hand, some objected on religious grounds to the operation's being performed under any circumstances. That was not the law either. "If pregnancy is likely to make a woman a physical and mental wreck," a doctor who operated in that belief did so

"for the purpose of preserving the life of the mother." The jury returned a verdict of "not guilty."

So far the case clears up one uncertainty of the law, but it gives no support to the view that abortion should be legal in a case of rape. The law of abortion is not in a satisfactory state and is under consideration by a committee appointed by the government. In a letter published in the medical journals Lord Horder, Havelock Ellis, Julian Huxley, Langdon-Brown, Prof. J. A. Ryle and other members of the Eugenic Society state that many arguments may be advanced for widening the grounds on which abortion should be permitted, but they deal only with the eugenic one. They think it should be permissible in cases of mental deficiency when the subjects are appropriate candidates for sterilization. This is the law in Denmark, where also incestuous union and rape are sufficient grounds.

Overseas Settlement and Population Trends

In the House of Lords an important debate took place on the recent report of the Oversea Settlement Board. The problem is difficult, as, on the one hand, in the present dangerous international situation it is more desirable than ever that the sparsely populated dominions and colonies should be peopled and, on the other hand, the prevalent unemployment makes the dominions unwilling to encourage immigration. The duke of Devonshire, undersecretary for dominion affairs, said that the white population of the empire was about 70,000,000, of which no less than 49,000,000 were congregated in the British Isles. Throughout the last century and up to the great war that white population was expanding rapidly and distributing itself over the empire. But for a variety of reasons the rate of expansion had been slowing down, and if the present tendency was continued the population would before many years become stationary and then rapidly diminish. The fall of emigration was great. In 1913 285,000 British left this country for the dominions and 61,000 returned, a net outward movement of 224,000. In 1937 the outward movement was only 26,000 and 34,000 returned, a net inward movement of 8,000. This was a very serious state of affairs.

Members of the Oversea Settlement Board were brought up against the question of population trends and took expert advice. They were told that to maintain a population a birth rate of about 19½ per thousand was necessary. In 1876 the birth rate of the United Kingdom was 36 but now was a shade over 15 and therefore below the replacement rate. There had been a similar drop in the dominions. In 1911 the birth rate in Australia and New Zealand was 27; today it had fallen to 17.1 in Australia and to 16.6 in New Zealand, in both cases below the replacement rate. In Canada the rate was 20, barely over replacement. But that was not entirely satisfactory, as the large birth rate was confined to one section, while the rest of the dominion had a very low rate. Only South Africa, with a rate of 24, promised to expand.

Osteopath Sent to Jail

A school teacher aged 23, who had suffered from diabetes since the age of 19, was under insulin treatment by a physician when a friend advised her to see an osteopath, who used a stethoscope, pulled down her eyelids and told her mother that she had never suffered from diabetes (*THE JOURNAL*, June 25). She was, he said, suffering from anemia, which might become pernicious. He ordered her to starve herself and take orange juice. The girl was so overjoyed that she ran out to her father, who was waiting in a car, and said "I have good news. I have not got diabetes and never had." Later her father telephoned to the osteopath that she had lost weight and disliked orange juice. The reply was "Splendid; tell her to grit her teeth, and continue the treatment until she sees me

on Thursday." By that day she had passed into coma. She died a week later in a hospital. At his trial for manslaughter the osteopath said that he found no external symptoms of diabetes and meant to carry out tests on the next occasion. In cross examination he admitted that he had no experience of diabetes. The judge asked why he did not say this when asked whether the girl had diabetes. He made no reply. He was found guilty and sentenced to six months' imprisonment.

Septic Infection at Necropsies

The Pathological Society of Great Britain has issued a pamphlet of valuable advice on the prevention of septic infection in the performance of necropsies. Proper care should be taken of postmortem gloves. When there are recent cuts or scratches on the hands it is inadvisable to perform necropsies. If during a necropsy the pathologist should prick himself however slightly, whether with a knife or on a jagged bone or tooth, even if he is in doubt whether he has been pricked at all he should stop at once, remove his glove and make the wound bleed by digital compression causing congestion, by swinging the arm, by sucking and by putting the hand in hot water. There should not be a minute's delay in carrying out these procedures, and, if possible, the necropsy should be completed by some one else.

PARIS

(From Our Regular Correspondent)

July 23, 1938.

Director of Pasteur Institute Honored in United States

During the recent visit of Dr. Louis Martin of Paris to the United States the degree of doctor of laws was conferred on him by both the University of Pennsylvania and the University of Montreal as a recognition of the many important contributions which he has made in the field of bacteriology. He was elected director of the Pasteur Institute of Paris after the death of Prof. Emile Roux.

Lister Medal Awarded to Prof. René Lériche

A jury including representatives of the Royal College of Surgeons of England and also that of Ireland, as well as of the faculties of the Universities of Edinburgh and of Glasgow, has awarded the Lister medal to Prof. René Lériche. This medal is considered a great honor and was awarded as a recognition of the work of Professor Lériche in experimental and clinical surgery.

A Peculiar Type of Echinococcus of the Liver

Reference has been made in a previous letter to the occurrence in eastern France of a form of echinococcus disease of the liver which is not only difficult to diagnose before operation but resembles so little the usual gross appearance of echinococcus disease of the liver as to be *unrecognizable* as such at operation. A recent case, reported by Drs. Gricouff and Agron at the June 15 meeting of the Académie de chirurgie of Paris, occurred in a section of France which is relatively far removed from the area in which the earlier cases were found. A woman aged 35, the wife of a farmer, had never been ill until January 1937, when she complained of fatigue, anorexia and occasional pain in the right side of the abdomen, all of six months' duration. Nothing objective was found at this time, but in October of the same year marked icterus and acholia of the stools were noted, which had been present for about six weeks. The liver was found to be greatly enlarged but there was no splenomegaly. X-ray examination for biliary calculi was negative, as was the Wassermann test. A preoperative diagnosis of calculous obstruction of the com-

mon duct was made. At operation, examination of the gall-bladder, extrahepatic biliary ducts and pancreas failed to reveal anything abnormal. On the anterior surface of the right lobe of the greatly enlarged liver, three nodules were noted, the largest being the size of a half-dollar (30 mm.). After incision of this nodule, a grayish green liquid escaped and a drain was inserted, from which a large amount of bile and blood escaped. The patient died about seven days after the operation. Histologic study of the hepatic tissue removed at operation revealed the typical picture of an alveolar type of echinococcus disease. Of eighteen cases of this unusual form thus far observed in France, thirteen involved patients who lived close to the Swiss frontier.

The question in such cases is whether *Taenia echinococcus*, which gives rise to the classic cyst formation, differs from the *tenia* which causes the alveolar type of change in such viscera as the liver. Prof. F. Dève of Rouen, who has studied the disease, expressed the opinion that the alveolar form also is due to *Taenia echinococcus*. In central European countries over 400 cases and in Russia about 209 cases of the alveolar type have been observed. Clinically the picture may resemble cirrhosis of the liver or, as in the case reported, obstruction of the liver or, as in the case reported, obstruction of the common duct. Most frequently the diagnosis of the alveolar type of echinococcus disease is made only after histologic study of the liver tissue. On gross examination the disease is characterized by the presence of a large number of contiguous minute cavities, each showing a more or less dry vesicular lining. In some reported cases it was possible to detect pulmonary metastases on x-ray examination.

The alveolar type has resisted all therapeutic measures, including operation.

BERLIN

(From Our Regular Correspondent)

June 27, 1938.

The German Society of Pharmacology

The German Society of Pharmacology met at the end of April in Berlin. Flury of Würzburg, the chairman, made the inaugural address, in which he outlined the scope of pharmacology. This field, he said, is concerned with all that lives, man, animals and plants, and also with all chemical substances as they relate to life. Pharmacology represents a wider aspect of physiology, in which unusual chemical influences, conditions and functions, together with their effects, are the material of study. Two principal provinces of pharmacology may be differentiated: pharmacetics and toxicology. The author emphasized that to be properly equipped as a specialist and teacher of pharmacology the student must undergo a long period of training.

The chief topic for discussion on the first day was local anesthesia. It was stated that besides the importance of the chemical composition the function must also be considered. A sharp distinction must be drawn between surface anesthesia and local anesthesia. Procaine hydrochloride, for example, because of its solubility in water, is unable to adhere to the surface membranes. As Fromherz pointed out, the central nervous system is ten times more reactive to local anesthetics than the peripheral nerves. All attempts at evaluation of the extent of the therapeutic effect of these substances have failed; in each case the clinician has the last word. An important consideration is the detoxicant property of the utilized substance. In resorption, diffusion apparently plays a less important part than the movement through the lymphatics. Kirschner of Heidelberg, a surgeon, gave the clinical lecture. He set forth the advantages of high pressure and local lumbar anesthesia as utilized by him. As contraindications of local anesthesia

he mentioned exophthalmic goiter (on account of the heightened sensitivity to epinephrine), toxic heart disease, nutritional disorders, tissue necroses and circulatory disorders (arteriosclerosis, hypertension and so on). The mortality of lumbar anesthesia amounts to about 1:3,300. The procedure is unsuccessful in about 9 per cent of the cases. Certain renal manifestations may appear, as well as paralysis of the muscles of the eyes, paralysis of the lower half of the body and meningism. On the other hand, Kirschner stated, the fact remains that no other type of anesthesia produces a similar relaxation of the abdominal walls.

The chief theme on the second day was the etiology of cancer. Butenandt discussed the cancerigenic carbohydrates from the chemical standpoint. These substances are of particular interest since their most effective representative, methylcholanthrene, shows itself to be related to that important group of substances known as the sterols (included in which are bilic acid, glandular preparations, corticosterone, vitamin D, digitalis glycosides, saponin and toad's venom). The author uttered a warning against the ill considered statement that estrogen is a cancerigenic substance. Gye of London delivered a lecture on the differentiation of external cancerigenic factors, or remote causes, and proximate, or intimate causes. According to his opinion, virus plays an important part as an intimate cancerigenic factor. The pharmacologic effects of benzopyrine were then thoroughly discussed. Professor Roessle, Berlin pathologic anatomist, then upheld, in opposition to Gye, the hypothesis of a diversified causation of cancer, which excludes the presence of virus as a universal "intimate cause."

On the third day the problem of coffee came in for thorough discussion. After a comprehensive general introduction by Straub of Munich, Eichler of Breslau submitted a detailed pharmacologic report. He pointed out that chronaxia of muscles is more plainly reduced than chronaxia of nerves. The completely developed fatigue is more quickly abolished by caffeine. Since the substance tends to increase the myocardial tonus, it is more fit for the overcoming of high resistance than for performance of greater volume-work. For the increase in secretion of gastric juice stimulated by caffeine, it is precisely the roasted products which are of importance. The rate of gastric evacuation remains unchanged. Some manifestations of diarrhea are perhaps ascribable to the presence of choline. In human milk 1 per cent of the administered caffeine remains undecomposed. The basal metabolic rate increases by from 6.5 to 23 per cent. Eichler has been unable to verify the damage to the germ cells following administration of caffeine in massive doses observed by Stieve, Berlin anatomist. Stepp of Munich read the clinical lecture. He recommends the use of caffeine in the treatment of cardiac disorders when the previous degree of digitalization is not known, as well as in the treatment of bradycardic types of insufficiency. Caffeine also acts favorably in cases of collapse from uncertain causes of asthenic persons with hypotonic manifestations. Patients with gastro-enterocolitis are unable to tolerate caffeine. In cases of gout and diabetes small amounts of caffeine are innocuous.

The president of the society provided an explanatory talk in which he emphasized that the coffee problem is not exclusively a caffeine problem. The chemical interrelation and the combined effect of caffeine and other ingredients of the coffee bean offer many unsolved problems. To what extent caffeine as a supplementary food is beneficial or deleterious to general health is, according to the present state of our knowledge, primarily a question of the amount of caffeine ingested. Additional factors of importance are the source of the coffee and the type of the roasting and other preparative processes. Clinical

data have shown that the ordinary use of coffee is unaccompanied by any harmful effects, either temporary or permanent.

AUSTRALIA

(From Our Regular Correspondent)

July 5, 1938.

National Health Insurance

The bill for national health and pensions insurance has now been passed by both houses of the commonwealth parliament. The scheme will come into operation in January 1939, and plans for its organization are already in progress. A royal commission is to be appointed to investigate fully the question of capitation fees payable to practitioners working under the scheme, and the British Medical Association in Australia is collecting statistical evidence to present to the commission in support of its claims for a higher capitation fee than that originally proposed by the government. Every member has been asked to supply any information he can which is relevant to the investigation, with particular reference to income as derived from lodge and private practice. The association intends raising an emergency fund of £20,000 to cover expenses such as statistician's fees and traveling expenses of members giving evidence. Each member of the association is expected to contribute £10 to this fund.

An adequate capitation fee is of vital importance to the profession in Australia, as over 80 per cent of the population are brought under the scheme. Five per cent of the remainder are unemployed, so that only 15 per cent of the people will receive medical treatment as private patients. It was pointed out in the first progress report of the national insurance commission in 1926 that 800 friendly society contracts were a burden for any one man working in a metropolitan district. This figure represents about 2,000 persons. It is estimated that about 10,000 visits a year would be required of such a practice, using the English panel experience of five visits a year per patient. The gross income under the national insurance scheme derived from 2,000 insured people would be £1,100. Estimating the minimum overhead expense in running a general practice at £500, this leaves a net income of £600 a year. Under the insurance scheme the average number of contracts per practitioner will be approximately 600, representing 1,500 people, 7,500 visits and a net income of £375 a year. Allowing for fees paid for extra services and the small amount of private practice, it would be difficult for any practitioner to receive a net income exceeding £600 per annum. Furthermore, with an income of £600, after a long and expensive training and after purchasing a private practice, no time and little money would be available for graduate study, and it would be difficult to maintain an efficient service for the community under such terms.

Calculation of the per capita payment was made by the government as follows: The average contract fee paid by friendly societies was taken as 29 shillings. The average number of persons covered by one contract fee was taken as 3.2. For extra service required under the insurance as against friendly society service, a ratio of 2 shillings in 9 shillings was agreed to. Twenty-nine shillings divided by 3.2 gave 9 shillings, which, together with 2 shillings for extra service, made 11 shillings the capitation fee. The assumption that the rates of payment for friendly societies contract practice were fair and adequate, especially when entirely changed conditions were to be dealt with, is itself questionable. Apart from this, a reliable calculation from census figures indicates that the family unit of 3.2 is too high an estimation and that a figure of not more than 2.5 should have been taken. The effect of this figure

is to change the per capita payment of 11 shillings to 15s. 3d. Moreover, insurance practice will be operating under much altered conditions. At present the inadequacy of friendly society practice is offset to some extent by income derived from private practice. Under the insurance scheme the ratio of contract to private practice will be greatly increased. The royal commission is to be appointed by the government and for this reason is considered by the British Medical Association to be in reality a court of inquiry appointed by one of the parties. Although members are prepared to present evidence to the commission, it is officially stated that they will not accept its findings unless an efficient medical service for the public and satisfactory conditions for practitioners are provided.

Queensland's Medical Problems

Plans for the complete reorganization of the hospital system in Queensland have been launched. They include the elimination of the honorary system of medical attendance and in many respects may indicate a complete change in the relationship between the state, the medical profession and the public. This move was intimated some months ago in an open letter to the profession signed by Sir Raphael Cilento, director general of health and medical services and honorary professor of social and tropical medicine in the University of Queensland. It was pointed out that the honorary system had been rendered an anachronism by the fact that complete medical service was beyond the means of 80 per cent of the people unless they were members of some contributory scheme and that the greater burdens laid on the middle class made the maintenance of health—that is, preventive medicine—and the restoration of health as a community measure—that is, cheap hospitalization—the main aspects of medical practice of the immediate future. It was implied that only by making medical service a government function could the position be satisfactorily dealt with. It was pointed out also that the health service of the future will inevitably conform to the governmental framework. There will be no interference with medicine as a science. What the public demands is the right to say not how medicine shall be practiced but how it shall be purchased and paid for.

For some years the state government has been seriously bent on a hospitalization program. The commonwealth government has now superimposed a scheme for national health insurance. The reorganization of the hospital system would suggest that the state intends to continue with its own design for medical treatment. Whether Queensland will be able to bear the economic strain of a large program for hospitalization in addition to that of national health insurance remains to be seen.

Diabetic Association

Steps are now being taken to form an Australian branch of the Diabetic Association. The parent body in London, founded about three years ago, consists essentially of persons with diabetes, together with several medical practitioners, dietitians, almoners and others who are in daily contact with sufferers from the disease. One of the chief objects of the association is the reeducation of all persons in the community as far as their outlook on persons with diabetes as a class is concerned and to spread the knowledge that such persons today are efficient and employable. The association also attempts to overcome the natural feeling of despair among patients at the discovery of their affliction. The effect of belonging to a well organized diabetic family facing a common difficulty is an important benefit, and practical instructions, hints and association news are conveyed to all members by the *Diabetic Journal*. The association provides information about the location of diabetic clinics and of boarding houses where diabetic persons receive special consideration, about

holiday camps for juvenile sufferers, about local sources of insulin and other equipment, and about district nurses who visit the infirm diabetic person. While there are several members of the parent association in Australia, the great distance from headquarters, together with the different conditions, makes it scarcely possible for them to obtain the full benefits of membership. It is to provide diabetic Australians with information and social care of the type supplied in England that a branch is being formed in Australia.

Contraception and Abortion

In Australia 31 per cent of all first births are the result of extramarital conception. Also, during the last twenty years the percentage of deaths from illegal operations has been multiplied by four; it now represents 20 per cent of total maternal deaths. These facts point to a loosening of moral standards, with consequent increase in intemperate contraception and criminal abortion for the failure of contraception. Intemperate contraception and criminal abortion have destroyed and are destroying the health of thousands of women. In the opinion of Dr. McLelland man is the defaulter. He considers that the feminist movement was a frank mutiny conditioned by man's failure in the primary duty of sustenance and protection of woman. The increasing extent to which women are employed in industry and commerce, the increasingly high wages paid to women and their insistent demands for independence, and the consequent unwillingness of young women in employment to enter matrimony are important factors in the increase of abortion. Added to these is the changed attitude of men toward women.

Marriages

PAUL B. FERRARY, Totowa, N. J., to Miss Ethel M. Kroger of Chevy Chase, Md., in Washington, D. C., July 20.

ELIZABETH FISHER to Mr. Homer Bush Martin, both of Regina, Sask., Canada, in Eau Claire, Wis., May 21.

HERBERT PERRIN HARKINS, Bala Cynwyd, Pa., to Miss Anna Catherine Shepler of Melrose Park, July 16.

FLOYD J. FOWLER, Akron, Ohio, to Miss Marian Vaughan Holoman of Rich Square, N. C., June 23.

WILLIAM BOYD TURNER, Carlisle, Pa., to Miss Katherine Anna Burr of Collingswood, N. J., July 9.

WILLIAM HANLON OATWAY JR. to Mrs. Margaret Ann Pyre Kenaston, both of Madison, Wis., June 4.

CHARLES FOSS FERGUSON to Miss Elsa Knutson Cosner, both of Boston, at Cambridge, Mass., June 16.

PAUL G. ALBRECHT, Cleveland, to Mrs. Evelyn Burford Randolph of New York, August 4.

REUBEN LOUIS KAUFMAN, Whittier, Calif., to Miss Lillian Skolnick of Los Angeles, June 19.

GEORGE W. WILHITE, Corsicana, Texas, to Miss Clara L. Mitchell of Taylor, March 31.

RAYMOND M. WALDKIRCH, Wayside, Neb., to Miss Fern Denys of Green Bay, June 9.

JOHN P. BARTLE, Langdon, N. D., to Miss Mercedes Mettel of Saskatoon, Sask., May 23.

CHESTER M. KURTZ, Madison, Wis., to Dr. ESTHER CALDWELL of St. Croix Falls, May 21.

IVAN B. TAYLOR to Miss Myra Elizabeth Williamson, both of Madison, Wis., May 28.

FREDERICK J. KALTEYER to Miss Marie Camblos, both of Philadelphia, July 14.

ROGER J. MINNER, Egypt, Pa., to Miss Helen A. Storm of Fullerton, July 16.

GEORGE O. DUNKER to Miss Constance Keyser, both of Milwaukee, July 9.

EDWIN A. SEIFERT to Miss Evelyn Rich, both of Glen Ridge, N. J., June 25.

FELIX F. HOROWITZ to Miss Martha Kramer, both of Brooklyn, June 14.

Deaths

Frederick Tilney, New York, since 1914 professor of neurology and neuro-anatomy at Columbia University College of Physicians and Surgeons, New York, died, August 7, aged 62. Dr. Tilney was born in Brooklyn, June 4, 1876. He received the bachelor of arts degree from Yale University, New Haven, Conn., in 1897 and the medical degree from Long Island College Hospital, Brooklyn, in 1903. During 1903 and 1904 he studied in Berlin. On returning to this country, he worked at the Long

FREDERICK TILNEY
1876-1938

Island College Hospital under the fellowship founded by Dr. Joshua M. Van Cott, in anatomy, embryology and nervous diseases. He became instructor in anatomy at Columbia University College of Physicians and Surgeons in 1909, about which time he reorganized the neurologic department of the Vanderbilt Clinic. From 1919 to 1924 he was director of neurology at the New York Post-Graduate Medical School. Dr. Tilney was a member of the Medical Society of the State of New York, the American Psychiatric Association, the Association for Research in Nervous and Mental Disease and the American Association of Anatomists and was also a past vice president and trustee of the New York Academy of Medicine and past president of the American Neurological Association. In 1935 he was appointed medical director of the Neurological Institute, after having been several years chairman of the institute's committee on medical research. He was also consultant in neurology at the Presbyterian, Babies, Roosevelt, Brooklyn, Methodist, Episcopal and the Greenwich hospitals. Dr. Tilney was chairman of the medical board of the State School for Delinquent Boys at Warwick, N. Y., founded in 1932. He accomplished research work, including the extensive Matheson Survey directed by the Neurological Institute to study cases of the socially maladjusted persons and criminals. In 1912 he took the degree of doctor of philosophy at Columbia for his thesis on "Contributions to the Study of Hypophysis Cerebri, with the Especial Reference to Comparative Histology," and in 1929 received the honorary degree of doctor of science. He was the co-author, with Dr. Henry A. Riley, of "The Form and Functions of the Central Nervous System"; author of a two-volume work "The Brain from Ape to Man" and of "Master of Destiny."

Pol N. Coryllos of New York; Université de Paris Faculté de Médecine, France, 1914; professor of surgery at the University of Greece from 1919 to 1923; came to the United States in 1923 and accepted the chair of professor of clinical surgery at Cornell University Medical College, a position he held for many years; clinical professor of thoracic surgery at the New York Polyclinic Medical School and Hospital; member of the American Association for Thoracic Surgery; fellow of the American College of Surgeons; received honors from several countries for his services during the World War; had been surgeon general in the Greek Army from 1919 to 1923; at various times director of thoracic surgery, Metropolitan Hospital and the Polyclinic, New York, and Sea View Hospital, Staten Island; thoracic surgeon to the Cornell Clinic; consulting thoracic surgeon to the Broad Street Hospital, New York, National Variety Artists Sanatorium, Saranac Lake, and Ulster County Sanatorium, Kingston; was director of surgery at the Veterans Administration Facility, Castle Point; author of "The Surgery of Pulmonary Tuberculosis"; and con-

tributed numerous articles to publications in this country and France; aged 57; died, July 26, in the Manhattan General Hospital of lobar pneumonia and cerebral hemorrhage.

Spencer Michael Free, Du Bois, Pa. College of Physicians and Surgeons, Baltimore, 1880; member of the Medical Society of the State of Pennsylvania; fellow of the American College of Surgeons; formerly lecturer on medical ethics and economics at his alma mater; inspector for the state board of health, 1887-1905; surgeon to the Du Bois and Maple Avenue hospitals; senior surgeon to the Adrian Hospital, Punxsutawney; consulting surgeon to the Indiana (Pa.) Hospital; formerly member of the school board; aged 81; died, May 16.

Arthur Matthew Kane, Brooklyn; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; fellow of the American College of Surgeons; adjunct professor of dermatology and syphilology at the New York Polyclinic Medical School and Hospital, New York; served during the World War; on the staffs of the New York Foundling Hospital and the New York City Hospital; aged 70; died, June 5, of pneumonia.

Alfred Edward Maumenee, Birmingham, Ala.; Medical College of Alabama, Mobile, 1905; member of the Medical Association of the State of Alabama and the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; on the staff of the Hillman Hospital; aged 58; died, June 5, in a hospital at Greenville, of heart disease.

Gilbert Dana Murray, Spring Lake, N. J.; Medico-Chirurgical College of Philadelphia, 1889; member of the Medical Society of the State of Pennsylvania and the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; aged 72; died, May 22, in the Wills Hospital, Philadelphia, of a cerebral hemorrhage.

John Lincoln Porter of Evanston, Ill., professor emeritus of orthopedic surgery at Northwestern University Medical School, Chicago, died, August 11, of coronary occlusion, aged 74. Dr. Porter was born in Alstead, N. H., July 2, 1864. He received the medical degree from Northwestern University Medical School in 1894. In 1900 he became professor of orthopedic surgery at the University of Illinois College of Medicine, where he served until 1917 when he became professor of orthopedic surgery at Northwestern. He was a

member of the American Orthopedic Association, past president and for many years treasurer; member of the Western Surgical Association, the Clinical Orthopedic Society and the American Academy of Orthopedic Surgeons and fellow of the American College of Surgeons. The silver jubilee of the Clinical Orthopedic Society in October 1937 was dedicated to Dr. Porter, who founded the society twenty-five years before, when it was known as the Central States Orthopedic Club. The John Lincoln Porter Memorial Lecture was established at the meeting. Dr. Porter was consulting orthopedic surgeon to the Evanston Hospital and St. Luke's Hospital, Chicago, and for many years attending orthopedic surgeon to the Cook County Hospital, Chicago. He was appointed a member of the advisory board of orthopedics during the World War and later was a major in the medical corps.

Charles Mortimer Culver, Delmar, N. Y.; Albany Medical College, 1881; member of the Medical Society of the State of New York, and the American Ophthalmological Society; translated under the supervision of the author, Dr. Edmund Landolt, "The Refraction and Accommodation of the Eye, and Their Anomalies"; aged 81; died, May 8.

JOHN LINCOLN PORTER
1864-1938

Daniel Bailey Hardenbergh * Middletown, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1891; formerly member of the board of education; on the staff of the Elizabeth Horton Memorial Hospital; aged 72; died, May 5, of cerebral arteriosclerosis and nephritis.

Robert Hughes Millwee * Dallas, Texas; Southern Methodist University Medical Department, Dallas, 1913; member of the Radiological Society of North America and the American College of Radiology; served during the World War; on the staff of the Dallas Methodist Hospital; aged 54; died, June 22.

Fred Baker, Point Loma, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1880; member of the California Medical Association; formerly member of the board of education of San Diego; aged 84; died, May 16, in the Mercy Hospital, San Diego, of intestinal obstruction.

Charles Menger Truschel * Wheeling, W. Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1904; served during the World War; aged 58; on the staffs of the Ohio Valley General Hospital and the Wheeling Hospital, where he died, May 22, of cerebral hemorrhage and hypertension.

Arthur John Stuenkel, Hinsdale, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; member of the Illinois State Medical Society; on the staff of the Elmhurst (Ill.) Hospital; aged 57; died, June 4, of chronic myocarditis and coronary sclerosis.

Frederick Edward Jones * Beaver Falls, N. Y.; Bellevue Hospital Medical College, New York, 1892; formerly secretary of the Lewis County Medical Society; for many years member of the board of education; on the staff of the Lewis County General Hospital, Lowville; aged 69; died, May 31.

James Sawyer, Mansfield, Ohio; Bellevue Hospital Medical College, New York, 1897; at one time member of the board of health of Asheville, N. C., and superintendent of health of Buncombe County; aged 64; died, June 2, in a hospital at Toledo of cerebral hemorrhage and arteriosclerosis.

William Williams Betts * Chadds Ford, Pa.; Jefferson Medical College of Philadelphia, 1907; past president of the Chester County Medical Society; aged 64; on the staff of the Chester County Hospital, West Chester, where he died, June 12, of coronary thrombosis and bronchial asthma.

James Williams Skebelsky * Chicago; Northwestern University Medical School, Chicago, 1907; formerly clinical assistant in dermatology and later instructor at his alma mater; on the staffs of the South Shore and South Chicago hospitals; aged 56; died, June 1, of coronary thrombosis.

Thomas Franklin Erdman, Reading, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1907; served during the World War; formerly assistant superintendent of the State Hospital, Norwich, Conn.; aged 54; died, May 21, of cirrhosis of the liver and ascites.

John Milton Mabbott * New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1884; formerly secretary of the International Spanish Speaking Association of Physicians, Dentists and Pharmacists; aged 75; died, July 1.

Francis McQuillan, Washington, D. C.; Georgetown University School of Medicine, Washington, 1903; member of the Medical Society of the District of Columbia; aged 60; on the staff of the Providence Hospital, where he died, June 10, of diabetes mellitus.

William Henry Abbott, Cambridge, N. Y.; Hahnemann Medical College and Hospital, Philadelphia, 1911; member of the Medical Society of the State of New York; aged 63; died, June 8, in the Mary McClellan Hospital of tuberculosis of the spinal column.

Thomas B. Miller, Richland, Ga.; University of Georgia Medical Department, Augusta, 1875; member of the Medical Association of Georgia; formerly mayor, member of the city council and board of education; aged 84; died, in June, of pneumonia.

John Henry Rose, Geneva, N. Y.; University of the City of New York Medical Department, 1892; served during the World War; aged 71; died, May 6, in the Clifton Springs (N. Y.) Sanitarium and Clinic of arteriosclerosis and pernicious anemia.

John Patrick Cantwell McManus, New York; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1897; for many years on the staff of the Bellevue Hospital; aged 71; died, June 22, in the Kingston (Ont.) General Hospital.

Isaac Wright Short, Elkhart, Ind.; Bellevue Hospital Medical College, New York, 1888; member of the Indiana State Medical Association; aged 74; died, June 4, of gastric hemorrhage, cerebral hemorrhage and diabetes mellitus.

Samuel Stalberg * Atlantic City, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; served during the World War; aged 59; was found dead, May 13, of illuminating gas poisoning, self administered.

Bancroft Frederic Bishop, Garrattsville, N. Y.; Long Island College Hospital, Brooklyn, 1886; member of the Medical Society of the State of New York; for many years county coroner and health officer; aged 79; died, May 10.

Harold Le Fevre Van Norstrand, Kingston, N. Y.; Long Island College Hospital, Brooklyn, 1921; member of the Medical Society of the State of New York; aged 41; on the staff of the Benedictine Hospital, where he died, May 15.

Thomas Jefferson Blackwell, Nacogdoches, Texas; Barnes Medical College, St. Louis, 1910; member of the State Medical Association of Texas; aged 65; formerly on the staff of the City Memorial Hospital; died, May 23.

Pedro Perea Fajardo, Mayaguez, P. R.; Ohio Medical University, Columbus, 1905; member of the Medical Association of Puerto Rico; part owner of the Mayaguez Sanatorium; formerly mayor; aged 58; died in May.

Guy Ira Robert Lawless, Danville, Va.; College of Physicians and Surgeons of St. Louis, 1922; Kansas City College of Medicine and Surgery, 1926; aged 42; died, June 13, of illuminating gas poison, self administered.

George J. Howe, Central Falls, R. I.; College of Physicians and Surgeons, Baltimore, 1892; member of the Rhode Island Medical Society; at one time school physician and coroner; aged 69; died, June 6, of myocarditis.

John Smith Redwine, Jackson, Ky.; Kentucky School of Medicine, Louisville, 1890; member of the Kentucky State Medical Association; aged 75; died, May 28, in the Good Samaritan Hospital, Lexington.

Daniel Harmon Thweatt, Eastaboga, Ala.; Birmingham Medical College, 1915; member of the Medical Association of the State of Alabama; aged 48; died, May 27, in the Citizens' Hospital, Talladega.

Nathaniel S. Greenwood, Philadelphia; Baltimore University School of Medicine, 1896; aged 71; died, May 27, in the Anderson Hospital of cardiac disease and prostatic hypertrophy.

Anna Minerva Stanton * Pittsburgh; Woman's Medical College of Pennsylvania, Philadelphia, 1897; aged 67; died, May 7, in the Western Pennsylvania Hospital of carcinoma of the rectum.

Joseph Clive Enos * Charleroi, Pa.; University of Maryland School of Medicine, 1904; aged 56; died, May 4, in the Allegheny General Hospital, Pittsburgh, of edema of the brain.

Mary Jones Brewster, Wellesley, Mass.; Woman's Medical College of Pennsylvania, Philadelphia, 1892; aged 76; died, June 9, of mesenteric embolus, arteriosclerosis and hypertension.

John Marten, Tolono, Ill.; Rush Medical College, Chicago, 1897; member of the Illinois State Medical Society; for many years president of the board of education; aged 80; died, June 7.

Carl Matthias Pohl * Chicago; Rush Medical College, Chicago, 1903; on the staff of the West Suburban Hospital, Oak Park, Ill.; aged 58; died, June 3, of cerebral hemorrhage.

George Robinson Pirie, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, Toronto, 1901; L. R. C. P., London, and M.R.C.S., England, 1915; aged 58; died, May 4.

Henry Nicholas Oestreich, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1900; aged 65; died, May 28, of chronic nephritis.

James M. Fallis, Luray, Kan.; St. Joseph (Mo.) Hospital Medical College, 1878; aged 90; died, May 22, in Ontario, Calif., of coronary thrombosis.

Frank Lossing Carpenter * Berkeley, Calif.; University of Buffalo School of Medicine, 1891; aged 70; died, May 17, of coronary thrombosis.

Lloyd Ellenberger Newcomer, Long Beach, Calif.; Rush Medical College, Chicago, 1903; aged 66; died, May 6, of cerebral hemorrhage.

Moses Chesley Roberts, Toronto, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1911; aged 58; died, May 23.

Joseph Louis Easton, Ayton, Ont., Canada; University of Toronto Faculty of Medicine, 1898; aged 69; died, May 5.

John Albert Gallagher, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1905; died, May 7.

Bureau of Investigation

CALDWELL'S SYRUP PEPSIN

The Federal Trade Commission Proceeds Against the Concern That Puts Out This Nostrum

A "patent medicine" of the laxative type has for years been sold under the misleading name "Syrup Pepsin." It is put out by "Dr. W. B. Caldwell, Inc.," of Monticello, Ill. For many years the name of the concern was Pepsin Syrup Company, but the name was changed to the present style about 1933.

Like the majority of "patent medicines" that have been in existence for thirty or more years, Syrup Pepsin, in its labeling, has undergone the usual changes from the "lie direct" to the "lie with circumstance." Before the days of the Food and Drugs Act of 1906, when lying on the label was merely immoral but carried with it no penalties, Syrup Pepsin was described as:

"A Cure for Stomach Troubles Such as Dyspepsia, Biliousness, Sick Headache, Sour Stomach and Heartburn; also Liver Troubles, Constipation and Ills Caused from Bad Digestion."

At that time the full title of the product was "Dr. W. B. Caldwell's Syrup Pepsin and Herb Laxative Compound." The words "Syrup Pepsin" were set in large, black-faced type (36-point capitals), while the words "Herb Laxative Compound" were set in very much smaller capital and lower-case type. After the Food and Drugs Act of 1906 penalized lying on the label, the claims were modified and it became no longer "A Cure" but:

"A Reliable Remedy for Constipation and Such Other Stomach Troubles as Dyspepsia, Biliousness, Sick Headache, Sour Stomach, Foul Breath, Heartburn, Liver Troubles, Etc."

Before the Food and Drugs Act the trade package described this preparation, in part, as "A Perfect Digestive Compound Composed of Pure Pepsin Combined with Plant Drugs Known to be Beneficial to the Human System . . ."

The 1938 carton describes the product as "Dr. W. B. Caldwell's Syrup Pepsin Combined with Laxative Senna Compound." The words "Syrup Pepsin" are still in the large 36-point, all-capital, black-faced type, but the supplementary description, "Laxative Senna Compound," is set in considerably larger type than the old description "Herb Laxative Compound" used to be, although it is still not as large as the "Syrup Pepsin" part of the label. The present carton no longer describes the preparation as a "Perfect Digestive Compound," but as "A Pleasant Laxative Compound," and the other claims are considerably milder, for today it is described as:

"A Laxative for Constipation and Associated Headaches, Sour Stomach, Biliousness, Colic and Cramps Due to Gas and Temporary Restlessness and Depression."

What Syrup Pepsin used to contain, nobody knew except the manufacturers and such chemists as might have analyzed it. The only information the old trade package used to give was that required under the Food and Drugs Act of 1906, namely, the alcohol percentage, which was given at that time as 8½ per cent. Today the alcohol is declared as 4½ per cent, and the package also states in small type that Syrup Pepsin contains 4 grains of pepsin to each ounce of syrup, while the "senna compound" is composed of senna, cascara sagrada, peppermint oil and aromatics. No quantities are given regarding the amount of senna and cascara, which are really the only drugs in the nostrum that mean anything.

There was a Dr. W. B. Caldwell and, in fact, he was one of the directors of the company many years ago. Dr. Caldwell died of senility in 1922. In spite of this fact, Syrup Pepsin was being advertised eight years after Caldwell's death with a large window display for drug stores in which Dr. W. B. Caldwell and a group of girls formed what was described as a "startlingly life-like presentation of the old doctor."

Nearly a quarter of a century ago (July 31, 1915) this department of THE JOURNAL published a brief article on this "patent medicine" and brought out the fact that the product was essentially a senna preparation. Some three years earlier (in 1912) Dr. L. F. Kebler, who was then chief of the Divi-

sion of Drugs of the Bureau of Chemistry of the Department of Agriculture, classed Caldwell's Syrup Pepsin among "products for which false or fraudulent claims are made." Dr. Kebler stated that the preparation was "an aqueous-alcoholic solution containing laxatives flavored with oil of peppermint. Pepsin is absent or not present in appreciable amounts." In 1915 the state chemists of Connecticut reported on Caldwell's Syrup Pepsin and stated that it was a senna preparation containing little if any pepsin.

The present case of the Federal Trade Commission against this nostrum is based, as all such cases under the law must be, on the charge that Caldwell's Syrup Pepsin is sold by methods that constitute unfair competition. The fact that a nostrum may be a fraud on the public did not, under the law, permit the Federal Trade Commission to act against it. It was only when preparations were sold under claims that brought them into unfair competition with other products of the same class that the commission could take action.

Among the false claims under which the commission charges that Caldwell's Syrup Pepsin is sold is one to the effect that the preparation is a "doctor's prescription." In the very nature of the case, a "patent medicine" cannot be a doctor's prescription, for a prescription is an order on a drug store for a certain drug or combination of drugs in certain definite proportions,

OLD

NEW

Greatly reduced reproductions of the old and present (1938) cartons. Note how the name "Syrup Pepsin" dominates the label; yet the pepsin is wholly without action as a laxative.

to be taken in equally definite dosage for some specified person at some particular time. It would be just as rational for a ready-made tailoring concern to put out a line of men's suits, all of one size and factory made, and advertise them as tailored to order.

Another claim made for the Caldwell nostrum was that it was not a habit-forming laxative. As all laxative drugs are potentially habit forming, the claim would be recognized as obviously false by physicians, but it would not be so obvious to the non-medically trained person. As Fantus has so well put it: "Cathartics are habit-producing drugs, admissible only in cases of temporary disturbance . . ."

But the gist of the Federal Trade Commission's case against Caldwell's Syrup Pepsin was the misleading name of the preparation. As William L. Taggart, attorney for the commission, pungently puts it in his brief: "The name Syrup Pepsin and advertising clearly indicate to a person that they would not be taking an ordinary laxative preparation, and they

are getting something more than a laxative, something which possesses a curative effect upon various ills of man and they should continually have it on hand and take it."

The Syrup Pepsin people introduced one scientific witness, a chemist, one Harvey A. Seil. The brief brings out the fact that "Seil wandered far from the field of chemistry to that of internal medicine." Of course, the Caldwell concern filed exceptions to the Trial Examiner's findings. These "exceptions," the commission's brief stated, were "full of loose talk and impertinence, and attempt to attack the good faith of the entire proceeding." One piece of "loose talk" by the company's lawyers in the exceptions reads:

"The recklessness of these charges raises the suspicion that they were made for an ulterior purpose possibly instigated by some individual or group who dislikes home remedies for common ailments and would like to have their sale forbidden."

The same old bugaboo that is always raised by "patent medicine" interests when the questions of fraud, misrepresentation and deceit are raised. The old charge—by implication—that the medical profession objects to the sale of "patent medicines" because it cuts into their business, when, as every physician knows, "patent medicine" advertising sends more patients to the doctor's office than does an epidemic. The charge is an ancient, evil smelling red herring drawn across a trail that is already sufficiently malodorous.

The article that appeared in this department of THE JOURNAL twenty-three years ago on Caldwell's Syrup Pepsin ended with this sentence: "The lack of any appreciable quantity of pepsin . . . would seem to indicate that the name would constitute misbranding under the federal Food and Drugs Act." We still think so, and it seems strange that Dr. Caldwell's Syrup Pepsin was never so charged under that law.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HAY FEVER AND ARTHRITIS

To the Editor:—A man aged 67 had more than average good health all his life but was a victim of hay fever. In the spring of 1936 he complained of some pain and slight swellings, at first principally in the joints of his fingers and in his wrists. In the last six months he has been confined to the house with a general arthritis. The teeth, tonsils and prostate have been investigated. In the fall of 1936 he had no symptoms of hay fever and again last year he was free from all symptoms of it. In forty-five years' experience I do not recall a similar case. Is it a mere coincidence or are there other cases like it? Could symptoms of hay fever again be activated in the patient and thereby, by the process of "shock," possibly have a favorable effect on the arthritis?

M. L. BARSHINGER, M.D., York, Pa.

ANSWER:—It is implied that there may be some connection between the appearance of the arthritis and the disappearance of hay fever and vice versa. Although the data are insufficient to allow one to be certain of the diagnosis, the patient presumably has generalized arthritis of the atrophic variety. Many investigators believe that atrophic arthritis, rather than being antagonistic to any allergic state, is in itself a manifestation of allergy and frequently associated with other allergic reactions. Some regard atrophic arthritis as a reaction to bacterial or food allergens. Some (Brown) contend that atrophic arthritis can be made worse by subsequent attacks of food hypersensitivity, but Bauer never saw a case of atrophic arthritis traceable to food allergy. Young noted that patients with atrophic arthritis are apparently abnormally susceptible to skin allergy (urticaria and allergic dermatitis) but not to hay fever or asthma. He could not prove any connection between arthritis and food allergy. In particular Wolf and Freeman have concluded that the relationship between arthritis and allergy remains unproved. In this case there is probably no direct connection between the appearance of the arthritis and the disappearance of the hay fever except that as the patient is confined to the house he is less exposed to those pollens which offend him. As people grow

older their hay fever often becomes less severe and the disease sometimes stops as suddenly as it appeared in youth.

EPINEPHRINE, MORPHINE AND SALICYLATES IN ASTHMA

To the Editor:—I have often heard physicians express the opinion that asthmatic patients should not have epinephrine and morphine administered together or following each other within a few minutes. Is this true? If so, what is the scientific basis for it? I have also heard that acetylsalicylic acid is contraindicated in asthma.

CLAUDE ANDERSON, M.D., Orlando, Fla.

ANSWER:—The older school of physicians used a great deal of morphine in the treatment of asthmatic attacks. Considerable success followed; relief was obtained in most cases; nausea and vomiting frequently followed, however, and the danger of hypersensitivity and of addiction were always present. But better methods of diagnosis and more experience have shown that morphine is the drug of choice in "cardiac asthma," that type of sudden dyspnea which occurs in older persons, especially those who have high blood pressure, nephritis or aortic regurgitation. Morphine in large doses works well in such cases and should be given promptly and in doses of from 0.016 to 0.03 Gm. (one-fourth to one-half grain) hypodermically, repeated if necessary. Epinephrine in this group is not indicated; in fact, it may be harmful.

In bronchial asthma, which usually occurs in children and young persons, epinephrine is the drug of choice; in most instances it works promptly and effectively and aside from temporary nervous effects it is relatively harmless and not habit forming. Unfortunately, in a small percentage of cases the asthma is not relieved and epinephrine may be injected frequently and with but little effect; the patients are often in an alarming condition: cyanosis, dyspnea, orthopnea, tachycardia, weakness and inability to take nourishment combine to alarm the patient, the family and the physician. When morphine is given the patient is frequently quieted for some time, but not rarely death ensues suddenly. The explanation is probably as follows: The patient is already in a state of anoxemia, as shown by cyanosis; his bronchial tubes are plugged by inspissated mucus (this has frequently been demonstrated at necropsy); the morphine probably lessens the cough reflex and so increases the obstruction; perhaps the morphine also acts by depressing the respiratory center of the brain. Morphine may also act allergically, causing an acute reaction. In any case the combination of epinephrine and morphine is fraught with danger. Most allergists believe that morphine should be used rarely in bronchial asthma and many never use it at all. In these severe cases of intractable asthma the specialists in this field are apt to try other measures; e. g., 1 cc. of epinephrine may be put into a 2 cc. hypodermic syringe; the needle is inserted intravenously and 1 cc. of blood is drawn up into the syringe; the mixture is then injected slowly into the vein. This works in many cases in which epinephrine subcutaneously fails. Other measures are general anesthesia as advocated by Kahn (*J. Allergy* 8:158 [Jan.] 1937) ether rectally, and various other sedatives. One reassuring factor is that if morphine is not used most of these patients sooner or later emerge from the severe phase of the attack and death is rare unless morphine is given. Many reports on this subject are in the literature; e. g., Dehner (*Klin. Wchnschr.* 6:1412 [July 23] 1927) warns against the use of morphine in discussing two fatal cases of asthma.

The use of acetylsalicylic acid in asthma depends entirely on whether or not the patient happens to be hypersensitive to this drug. If he has previously taken it without trouble he can almost certainly continue using it. Many patients are much benefited by its use. But if the patient has an idiosyncrasy to the drug he must avoid it as he would the most drastic poison, because even a grain or less may throw him into an acute attack of bronchial asthma even to the point of fatality. Not only must he avoid acetylsalicylic acid but also drugs which contain it, such as "Alka-Seltzer." Other coal tar products must be used cautiously, although patients hypersensitive to acetylsalicylic acid can usually tolerate aminopyrine, acetanilid

and sodium salicylate. A wise rule before prescribing is to question all allergic patients as to possible drug idiosyncrasies. Such care pays dividends. Many reports on idiosyncrasy to acetylsalicylic acid are in the literature. Duke (*J. Allergy* 4:426 [July] 1933) suggests testing allergic patients by placing a minute granule of acetylsalicylic acid beneath the tongue. Hypersensitivity will be shown within a few minutes by the usual symptoms of drug idiosyncrasy: angioneurotic edema, urticaria, rhinitis or asthma. Further symptoms may be prevented by rinsing the mouth with dilute acetic acid (vinegar). Prickman and Buchstein (Hypersensitivity to Acetylsalicylic Acid [Aspirin], *THE JOURNAL*, Feb. 6, 1937, p. 445) recently reviewed the subject and reported cases of their own.

TREATMENT OF BUERGER'S DISEASE

To the Editor:—What is the best treatment for Buerger's disease?

JOHN W. BOLEN JR., M.D., Beckley, W. Va.

ANSWER.—The use of tobacco in any form should be denied every patient who has thrombo-angiitis obliterans. It is important that the feet be cared for properly if gangrene is to be prevented. A regimen similar to that described for the care of the feet in diabetes is advisable. Preparations containing iodine, merthiolate, sulfonaphthol, phenol (carbolic acid), cresol and saponated solution of cresol should be avoided, as they may cause ulceration or gangrene. Trichophytosis should be actively treated but not with preparations containing salicylic acid, as they may cause ulceration. A safe method of treatment is to soak the feet for half an hour twice daily in a 1:8,000 solution of potassium permanganate.

Local application of heat is advisable and may be applied in the form of radiant heat from carbon filament bulbs placed in a cradle or baker. The temperature about the feet should not exceed 105° C. Exposure to this temperature for an hour two or three times a day is advisable. Warm sitz baths, using water as warm as can be tolerated comfortably, may be used for periods of ten to twenty minutes one to three times each day. Electric pads or hot water bottles should never be applied directly to the skin. Postural exercises may be helpful. The patient should elevate the extremities for one minute, then place them in the dependent position until the rubor becomes maximal and then lie with them in a horizontal position for one minute. These procedures should be repeated five times, two or three times a day. Contrast baths may be advisable. There should be two containers, each large enough to immerse both feet to the midleg. In one container is placed cold water of from 40 to 50° F. and in the other warm water of from 102 to 105° F. The feet are alternately immersed in the water in each container for one minute during a period of about fifteen minutes. This procedure can be repeated two or three times a day. In some instances intermittent suction and pressure (passive vascular exercise) treatment should be carried out for two or three hours daily. Some physicians believe that this method of treatment is valueless, but it is worth a trial in most cases. Intermittent venous obstruction is considered advisable by some physicians. While machines are available which perform this treatment automatically, it can be carried out by placing the cuff of a sphygmomanometer about the thigh or arm. The cuff is inflated to a pressure of about 80 mm. of mercury for two minutes and then deflated for two minutes. This treatment should be carried out for a minimum of four or five hours daily. Some authors feel that a diet high in calcium or the addition of half a teaspoonful of calcium lactate or a heaping teaspoonful of calcium gluconate is advisable an hour before meals. Injections of 250 cc. of 2 per cent solution of sodium citrate as often as every day or as infrequently as two or three times a week for a considerable period may help. The solution is injected at the rate of from 7 to 8 cc. a minute. Injections of hypertonic solutions of sodium chloride may aid. In cases of thrombo-angiitis obliterans without gangrene these injections are given in amounts of from 250 to 350 cc. of a 3 to 5 per cent solution twice or three times a week for about three months. Then the frequency of injection is gradually diminished for about six months. In cases of gangrene, injections are given three times each week until healing occurs or until hopelessness of further treatment has been established. The solution should be injected through a 19 gage needle at the rate of about 30 cc. a minute. One of the best methods of increasing the circulation in thrombo-angiitis obliterans is the repeated induction of fever by means of the intravenous injection of typhoid vaccine. For the convenience of administration, a stock solution should be diluted with physiologic solution of sodium chloride so that 1 cc. contains 100,000,000 killed bacteria. The desired reaction is elevation of the oral temperature to from 101 to 102° F. Chill, headache and malaise may result. Excessive elevation of the oral temperature, severe

chills and serious malaise are not necessary and are to be avoided if possible. The original injection contains from 15,000,000 to 25,000,000 bacteria for a man and from 10,000,000 to 15,000,000 for a woman. Ordinarily, each subsequent dose is increased by from 15,000,000 to 25,000,000 bacteria but the amount injected depends on the reactions. If the reaction to any injection is too severe, the subsequent injection should be increased only slightly or not increased at all. If the reaction is too mild, the next injection should contain from 25,000,000 to 50,000,000 bacteria more than the preceding one did. Injections may be given once or twice a week for six or eight weeks, after which a rest period of several weeks is advisable before another course is begun. Contraindications to the intravenous injection of typhoid vaccine are advanced debilitating diseases, diseases of the coronary and cerebral arteries, chronic nephritis, myocardial insufficiency, active pleurisy or pericarditis, latent or quiescent appendicitis, and cholecystitis. Vasodilating drugs are ordinarily of little use in the treatment of thrombo-angiitis obliterans, since the vasodilating effects are ordinarily slight and transient.

Intermittent claudication can be treated by the use of tissue extracts, most of which do not cause any significant improvement in circulation but only allow the patient to exercise longer before the distress of claudication occurs. Pancreatic tissue extract, supplied by Sharp and Dohme under the label "tissue extract number 568," can be injected into the deltoid muscle in doses of 3 cc. about twice a week.

Severe pain may affect the extremities when the patient is at rest, when trophic changes are present or when the skin is unbroken. In many instances morphine or dilaudid must be used, but habituation should be avoided. Codeine sulfate is efficacious in many instances. The artificial induction of fever by means of the intravenous injection of typhoid vaccine may produce startling relief. Other measures such as intermittent suction and pressure, intermittent venous obstruction and intravenous injection of solution of sodium citrate and sodium chloride should be tried. When pain does not respond favorably to these measures and the patient loses morale and weight and is unable to sleep, section or crushing or injection of alcohol into the posterior tibial, peroneal and sural nerves may produce anesthesia of the skin and relieve pain. In other instances it is advisable to inject alcohol into the spinal canal for the purpose of affecting the posterior nerve roots. Either of these procedures should be carried out only by experienced surgeons.

Gangrene should be kept clean and the extremity should be soaked for from two to four hours daily in a warm saturated solution of boric acid, a 1:8,000 solution of potassium permanganate or a 0.5 per cent solution of chloramine-T. In some instances débridement may be advisable. It is only rarely that a toe can be successfully amputated, for the incision ordinarily does not heal. When fingers are amputated, on the contrary, the wounds almost invariably heal. Other measures, such as those mentioned in the preceding paragraphs, should be used. When massive gangrene affects an entire foot, amputation is ordinarily the best solution. In about 80 per cent of the cases healing follows amputation of the extremity below the knee but it is occasionally necessary to perform reamputation above the knee. Necessity for amputation of the forearm has never been observed.

Removal of the sympathetic nerve supply to the extremity is performed for the single purpose of increasing the blood flow. This procedure does not ordinarily affect intermittent claudication or prevent recurrence of the superficial phlebitis or progression of the disease. It does, however, increase the blood supply to nearly maximum and minimizes the danger of gangrene necessitating amputation. It should be carried out only when trophic lesions are minimal and healing, or when they are entirely absent and when pain which occurs during rest has been almost entirely relieved or is entirely absent. Whether or not the blood supply can be significantly increased by sympathectomy can be determined by thermometric study of the extremity following the artificial induction of fever by typhoid vaccine.

REACTIONS AFTER TETANUS ANTITOXIN

To the Editor:—A cattle ranchman, aged 24, was using a pocket knife to trim a horse's tail; he dropped the knife, which stuck deeply into the calf of the leg, making it bleed profusely. This was June 10. A doctor gave him tetanus antitoxin (probably 1,500 units) into the outer upper left arm. He didn't scrub the arm with a brush and soap and water but used only an alcohol swab. During the night of June 10 the patient's arm began swelling and itching; it became swollen to the finger tips and brawny and red. The next day at noon the pulse rate was 104, the temperature 103 F. The eyes were red. The head ached. The neck was slightly stiff. There was paralysis of the left arm. The shoulder was painful and lame. The right arm was swollen and he had severe backache and pain in both knees and calves of the legs. There were anorexia, restlessness and sleeplessness. The treatment was hot water baths including the shoulder and entire arm alternating with cold. Ten cc. of metaphen was injected intravenously with magnesium sulfate by mouth. Two dozen tablets of sulfanilamide were given, three tablets three times a day. Sedatives were administered for rest. Forced fluids and a nourishing liquid diet (beef broth, oyster soup) were prescribed. There was an improvement overnight, the temperature decreased and the swelling and redness of the arm disappeared; but the calves of the legs and knees "feel drawn" and the patient walks "string haltered," raising the knees high at each step. That is the only remaining infirmity. What causes it? Could the tetanus antitoxin have been old or polluted? I don't know what brand was used or how fresh it was. Should I give him more? Are the "lame legs" beginning tetanus or the result of a beginning general septicemia affecting the knee joints and calves? Shall I take a watchful expectancy attitude or give him more metaphen and fresh antitoxin? An outline of treatment with diagnosis of his gait would be appreciated. The punctured wound in the limb is healing and there is no pus or any drainage. The wound was not swabbed out, as it was bleeding so much and was only the size of a small knife blade. He is afraid of any more needle punctures and of tetanus antitoxin.

M.D., Colorado.

ANSWER.—This patient probably suffered an early serum reaction. Serum sickness as a rule is much later in appearing than in this case but if the patient is congenitally sensitive to serum or if serum has been administered previously, the symptoms may come on with almost the rapidity of anaphylactic shock. It is not necessary for the serum to be old or contaminated to produce such a reaction. All the symptoms described, with the exception of the gait, are commonly seen in serum sickness. Transient neurologic phenomena, which would account for the peculiar gait, have been infrequently described in this country but have been rather frequently mentioned in the French literature.

It is difficult to explain the lame legs as a phenomenon of tetanus. They were present the day after the accident. Tetanus as the result of a wound of the leg in an adult is extremely unlikely to appear in less than a week. Tetanus in any case earlier than three days is a great rarity. A beginning general septicemia seems equally unlikely. Such an event should be accompanied by more severe general symptoms. It is altogether likely that the residual symptoms will gradually disappear without treatment.

More antiserum would be likely to produce a reaction even more serious than the initial one. Fatal collapse has followed such procedures. In the World War tetanus was nearly abolished by the use of a single prophylactic injection of antiserum. Tetanus is rather uncommon in persons who are constantly exposed to the organism. These facts would make the appearance of tetanus in this patient a rather remote possibility. In spite of this feeling of relative safety, the patient should be watched for several weeks. If frank symptoms of tetanus appear he should be vigorously treated, but he must be desensitized before any quantity of serum is administered.

ALKALOSIS

To the Editor:—Please give the physiologic-chemical reactions that occur when one gives (1) saline solution, (2) Ringer's solution and (3) Hartmann's solution in (a) alkalosis and (b) acidosis.

M.D., Tennessee.

ANSWER.—Alkalosis designates an increase in the bicarbonates (alkali reserve) of the blood above the normal level, as from ingestion or administration of alkalis to the extent that elimination by the kidney or bowel is not sufficient to prevent accumulation in the blood, or represents an abnormal increase in the pH of the blood, as from overventilation (excess breathing) leading to excess loss of carbon dioxide from the blood with the resulting reduction of carbonic acid in proportion to bicarbonate (uncompensated gaseous alkalosis). Treatment of alkalosis, varying with the condition which produced it, is directed toward the correction of the disturbed acid-base balance and dehydration. If the condition is due to excessive alkali ingestion, the alkali should be discontinued and saline solution should be forced by mouth to enable excretion of the excess alkali. Physiologic solution of sodium chloride in large amounts will

help to restore the normal electrolyte pattern in the blood. Alkalosis produced by vomiting, in which severe chloride loss and dehydration occur, should be treated by intravenous injection of large amounts of saline solution (1,000 cc. of 1 per cent sodium chloride every three hours). Alkalosis due to over-ventilation (apapnic alkalosis) may be relieved by rebreathing a 5 per cent carbon dioxide-oxygen mixture.

Acidosis is the term applied to the diminution to a subnormal level of the reserve supply of fixed bases in the blood but has been loosely used to indicate also a decrease in the pH of the blood. Only severe acidosis is of clinical importance, as in diabetes mellitus, in the terminal stages of chronic nephritis, in Asiatic cholera and in shock, burns, poisoning and fasting. Acidosis is most commonly caused by diabetes in which there is excessive production of beta-hydroxybutyric and acetoacetic acids from deranged fat and protein metabolism (the condition for which Naunyn originally introduced the term acidosis). In almost all cases of acidosis there is dehydration and loss of base, and treatment consists in rapidly restoring the water balance and acid-base equilibrium to normal by administration of large amounts of a solution which supplies base and water, thus increasing the blood volume, blood pressure, plasma carbon dioxide and urinary output, alleviating coma and offsetting the danger of shock. In mild acidosis the patient is not in coma; sodium bicarbonate is therefore not necessary and considerably less solution is required for restoration of the normal water and base balance.

It may be noted from the foregoing that sodium chloride solution (1 per cent), Ringer's solution (0.65 per cent sodium chloride, 0.030 per cent potassium chloride, 0.025 per cent calcium chloride, 0.020 per cent sodium bicarbonate and 0.001 per cent sodium biphosphate) and Hartmann's solution (lactate-Ringer's solution; 0.20 per cent lactic acid as sodium lactate, 0.6 per cent sodium chloride, 0.04 per cent potassium chloride and 0.02 per cent calcium chloride) all have their places in the treatment of alkalosis or acidosis. Sodium chloride solution overcomes the dehydration and salt depletion; Ringer's solution, in addition to overcoming water and salt depletion, supplies bicarbonate; lactate-Ringer's solution supplies water, base chloride, base bicarbonate and antiketogenic effect. Sodium chloride solution in alkalosis and mild acidosis and Ringer's solution in severe acidosis are the fluids of choice. Lactate-Ringer's solution may be used for the treatment of dehydration with a moderate degree of acidosis or alkalosis.

SODIUM THIOSULFATE IN ARSENIC POISONING AND RAYNAUD'S PHENOMENON

To the Editor:—I would appreciate information as to the treatment of Raynaud's disease and arsenic poisoning with sodium thiosulfate.

R. O. WHARTON, M.D., Gary, Ind.

ANSWER.—Diametrically opposed opinions have been held by various authors relative to the efficacy of the administration of sodium thiosulfate in the treatment of poisoning with arsenic. The subject has been reviewed by Ayres and Anderson (*THE JOURNAL*, March 19, 1938, p. 886), who have made determinations for arsenic on the urine of forty-nine patients with a variety of cutaneous disorders for which arsenic was suspected as being a possible etiologic factor. Of these patients 8 per cent did not have arsenic in the urine either before or after injection of sodium thiosulfate. The urine of 12 per cent showed less arsenic after than before injection of sodium thiosulfate, and the urine of 80 per cent showed an increase of arsenic after injection of sodium thiosulfate. These authors consider it unequivocally proved that an increase in the excretion of urinary arsenic usually follows the injection of sodium thiosulfate. Most students of the subject agree that in arsenism the use of sodium thiosulfate is of value but clinical experience indicates that it is most efficacious in treating the acute manifestations of arsenic poisoning.

The inquirer's question intimates that there is a relationship between arsenic poisoning and Raynaud's phenomenon. That such a relationship exists has been contended by Kraetzer (*New York State J. Med.* 35:1130 [Nov. 15] 1935). He treated seven patients with Raynaud's phenomenon, the urine of all of whom contained arsenic after treatment with sodium thiosulfate. In all instances Raynaud's phenomenon disappeared entirely or was greatly improved after treatment over varying periods with sodium thiosulfate. Another investigator studied the urine of eight patients following the intravenous injection of sodium thiosulfate and was unable to demonstrate significant amounts of arsenic in the urine of any of them. Kraetzer feels that lead may occasionally be the etiologic basis for Raynaud's disease, but another investigator who has treated more than 500 cases of carcinoma with lead has noted that none of the patients so treated had manifestations of Raynaud's disease. The subject

is far from settled but it seems desirable to try the effect of intravenous administration of sodium thiosulfate on the Raynaud phenomenon. The drug should be given intravenously twice a week in doses of 0.5 Gm. The solution should be made up fresh from highly purified crystals.

APPENDICITIS AND DISEASE OF LUNG

To the Editor:—During the last four years I have operated in four cases of gangrenous appendix. In each case I was hesitant about operating because of rales in the base of the right lung posteriorly. The rales were of the fine crepitant type; being in doubt as to whether I was dealing with pneumonia or appendicitis, I was always hesitant to operate until signs became definite. In the last case an embolism occurred in the base of the right lung posteriorly two days after operation. It was a large occlusion involving about half of the lung. Is there any connection between a gangrenous appendix and the right side of the chest? Is there any weakness which would cause the right lung to become involved after an operation of this sort? All these operations were done under spinal anesthesia and all the appendixes were definitely gangrenous.

L. C. POMAINVILLE, M.D., Wisconsin Rapids, Wis.

ANSWER.—There is no known direct connection between appendicitis and pathologic conditions in the right chest. The fact that the appendix was gangrenous does not alter the connection. Rarely a subphrenic abscess will occur after a ruptured appendix and will secondarily involve the pleura above the diaphragm. In the case described as an embolism in the base of the right lung posteriorly it is not impossible that this was rather an atelectasis or partial collapse occurring as a result of a mucous plug in the bronchus. Atelectasis may occur with spinal anesthesia and is not really infrequent. The best prophylaxis against massive collapse (atelectasis) is the avoidance of undue preliminary medication. In some places morphine has been abandoned entirely. Differential diagnosis between pneumonia and appendicitis is usually not difficult except in young children. In adults, in cases of pneumonia, the entire right rectus is usually rigid, which is less frequently the case in appendicitis. In addition, of course, there are abnormalities of the lung observed through auscultation, increased respiratory rate, and possibly a cough.

RECURRENT CORNEAL ULCERS

To the Editor:—A woman, aged 63, has had recurrent corneal ulcers in each eye; about five in one year. For the last two months I have given her ABD capsules twice a day but this week she has had a recurrence. The urine and blood are normal in all respects. The blood pressure is normal. She is 5 feet 3 inches (160 cm.) tall and weighs 130 pounds (59 Kg.). She had been well until two years ago, when she began to have pain in the upper left quadrant and lost 30 pounds (13.6 Kg.) because certain food distressed her. A complete gastrointestinal examination was made and the last part of the transverse and the first part of descending colon were found to overlap each other entirely. Stomach analysis gave negative results. She was given a low residue diet and she has gained 10 pounds (4.5 Kg.) and has little pain in the abdomen. Is it possible that this intestinal condition has anything to do with the frequent corneal ulcers? Would there be any way to prevent these recurrences or anything further to look for as the cause of this condition?

LOUIS S. BOEN, M.D., Conway, Mass.

ANSWER.—If the recurrent ulcers are of the usual catarrhal type they may be caused by an accompanying conjunctivitis. The use of 0.2 per cent zinc chloride solution three times a day may clear up the conjunctivitis and prevent recurrences. Larger doses of vitamin A may also be of benefit, twenty drops of halibut liver oil or sixty drops of carotene a day being probably sufficient. Blepharitis, if present, should be treated. The intestinal condition may be an indirect factor by lowering the general nutrition.

INTOXICATION OR CEREBRAL CONCUSSION

To the Editor:—How often does cerebral concussion simulate intoxication? I am interested in knowing how often patients held for intoxication are later found to be suffering from cerebral concussion.

M.D., Wisconsin.

ANSWER.—Simple cerebral concussion rarely if ever simulates intoxication. When it does occur it should be relatively easy to differentiate between them. In simple concussion of the brain without fracture or compression there is usually some disturbance of consciousness ranging from momentary "seeing stars" to temporary unconsciousness. Severe or prolonged stupor or deep coma is not characteristic of simple concussion. These conditions indicate much more grave brain damage or injury. In intoxication the breath has the characteristic odor, the stomach content has alcohol in it and the blood stream is positive for alcohol. There are usually multiple and variable neurologic signs of alcoholism. These are tremulous hands,

positive Quinquaud's sign, tremulous speech, tremulous tongue, rapid pulse and a varied type of mental and emotional behavior ranging from violence and garrulousness to an ordinary depressed or sleepy state. Many cases of concussion of the brain result from the indiscreet use of alcohol and an automobile. In a large hospital of 3,300 beds there is an average daily admission of about ten cases of acute alcoholism with lacerations of the scalp. These patients are observed for forty-eight hours for development of complications or objective evidence of organic disease. If none occur at the end of this time they are sent home with the advice to return for a second examination in one week. It is a rare occurrence to have a person held in a police station for intoxication when that person is suffering a cerebral concussion. Severe craniocerebral injuries in association with alcohol must be treated and observed for a period from fourteen to twenty-one days, depending on the extent of craniocerebral damage.

SODIUM TETRATHIONATE IN CARBON MONOXIDE POISONING

To the Editor:—In August 1933 a report was published in the local newspaper referring to the chemical "Sodium Tetra-Thionate," which was used as a specific therapeutic agent in carbon monoxide poisoning. I have never seen any reports published in the literature and no further mention has been made of this agent. Since I have a supply of this substance and since I have a fair number of these cases, I would appreciate any information you can supply as to use, mode of administration, action and dosage of this drug.

M.D., New Jersey.

ANSWER.—No reports on this subject have been discovered in scientific or medical literature. There is no general reason to suppose that so mild an oxidizing agent as sodium tetrathionate would be of any value in carbon monoxide poisoning. Its effect, like that of methylene blue, might tend to produce methemoglobin and thus exacerbate the ill effects of carbon monoxide.

MALIGNANT HYPERTENSION AND TERMINATION OF PREGNANCY

To the Editor:—A white woman, aged 29, four and one-half months pregnant, has an atrophied and functionless left arm and drags the foot when she walks. This followed a hemorrhage into the internal capsule in August 1937. The blood pressure was 230 systolic, 140 diastolic. The urine was normal. In spite of the fact that she was extremely desirous of having a child, even at the expense of her own life, I demanded the termination of the pregnancy and she reluctantly consented. She was admitted to a hospital in a neighboring town, but after the consulting surgeon examined her he thought best to watch her carefully until seven and one-half to 8 months and then do a cesarean section. If she developed signs of increasing toxemia, he maintained that the abortion at that time would be attended by no more danger than if it was done now. I myself feel that if this woman is allowed to continue her pregnancy to eight months she will certainly have a permanently damaged kidney function or an exaggeration of her vascular condition. The surgeon argues that if she were three months pregnant or less he would terminate the gestation, but since she has progressed to four and one-half months he feels that termination would be as dangerous as letting her go on to eight months. Please give me your opinion.

M.D., Ohio.

ANSWER.—In all probability the patient has an essential hypertension of the malignant type. The cerebral accident at the early age of 29 would indicate such a diagnosis. Furthermore, the absence of urinary abnormalities lends credence to this view.

It has been usually noted that patients with such severe hypertension are not likely to continue their gestation to term. One of several accidents is likely to occur. The most frequent complication is the death of the fetus in utero. Occasionally a premature separation of the placenta, abruptio placentae, supervenes in the course of the pregnancy. In the event that the patient successfully carries the baby to term or near term, the fetus is likely to be small, underdeveloped and immature as a result of extensive infarction of the placenta. For these reasons the early interruption of pregnancy is usually considered the safest procedure.

In this case the decision as to when to terminate the gestation will probably not affect the prognosis for the mother and child appreciably. In any event, it is unlikely that a living child will result. The artificial interruption of pregnancy at this time is usually difficult, and operative manipulations carry considerable risk in such cases. It is doubtful whether the artificial termination at or near term will increase the hazard. The likelihood of permanent kidney damage is not an important factor to this seriously ill patient. The hypertension, however, will probably become more severe. Another and perhaps fatal cerebral accident may occur at any time. The patient should be watched carefully and in the event that fetal death occurs a spontaneous evacuation of the uterus may take place. This should offer the best prognosis for the patient.

EFFECT OF OVARIES ON PITUITARY FUNCTION

To the Editor:—Is there any evidence that the ovaries have an inhibitory action on pituitary functioning? A woman, aged 47, received high voltage roentgen therapy (irradiation over the pelvic region) five years ago, to bring about a cessation of menstruation. Her menstruation had been prolonged and excessive for several years previously. Shortly after the roentgen exposure she began to show signs of what has now developed into a well established case of acromegaly. Could there be any connection between the roentgen therapy and the development of the disease? Would high voltage roentgen therapy of the pituitary be advisable at this time?

M.D., Ohio.

ANSWER.—The ovaries exercise an inhibitory action on pituitary function. This is demonstrated not infrequently when ovarian function ceases. Even in the normal menopause there is unquestionably a temporary increase in pituitary function. This is more marked in the induced menopause, whether brought about by surgery or by irradiation. This also is usually temporary in nature.

In the case cited it is possible that the irradiation over the pelvic region which brought about the cessation of menstruation just constituted the last straw which is responsible for precipitating the acromegaly. If this was the case there must have been a preexisting tendency to hyperfunction of the pituitary which became exaggerated with the induced menopause. The extent of the acromegaly will probably be the determining factor as to whether or not roentgen therapy at the present time is advisable. If so advanced as to give rise to intractable headache or visual disturbances, the irradiation would probably prove futile. If in a milder form, roentgen therapy is justifiable and might prove beneficial.

COMPLICATED CATARACT

To the Editor:—A man, aged 48, was referred to me to have a cataract removed. Adhesions between the iris and the anterior capsule of the lens are so adherent that it is impossible to dilate the pupil. The patient has become neurotic since the accident to his eye and thinks that if the cataract is removed he will become normal again. Would you think it justified to attempt to do a cataract extraction on this patient?

M.D., Michigan.

ANSWER.—There are so many points involved in dealing with a question of this kind that generalization is extremely difficult. In the first place what was the cause of the cataract and consequently what are the chances of useful vision provided a successful extraction is performed? In the second place, this is evidently a cataracta complicata and the chances for successful operation are somewhat poorer in this form. It might be mentioned that extraction of the lens through a round pupil is highly desirable in a neurotic person of 48 but seems hardly possible in the case as described. In the third place, the mental aspect of the patient seems to be none too favorable for the considerable tension and anxiety that the operation induces. Finally, the patient must be disabused promptly of the idea that subsequent to the extraction he will have an eye that will function as normally as before. When all this has been explained to the patient so that he can know what he has to look forward to, the operation may be undertaken if still desired. The mere presence of posterior adhesions does not preclude the likelihood of a successful extraction.

PARALDEHYDE AND ANALGESICS IN LABOR

To the Editor:—Is it safe to give paraldehyde orally in obstetrics? I notice that it is being used in 4 and 5 drachm doses with the same amount of aromatic elixir to produce obstetric amnesia. Would you please discuss the use of it?

M.D., West Virginia.

ANSWER.—A patient of average weight can be given 15 cc. (4 or 5 drachms) of paraldehyde orally without endangering life. This dose will produce considerable obstetric amnesia. As a rule, paraldehyde is combined with some other drug to provide more adequate relief from pain. Its administration in benzyl alcohol by rectum has been suggested (Kane, H. F., and Roth, G. B.: *The Relief of Labor Pains by the Use of Paraldehyde and Benzyl Alcohol*, *THE JOURNAL*, Nov. 21, 1936, p. 1710).

The problem of providing relief from pain in childbirth is difficult. A large number of sedative and analgesic drugs have been suggested. The most common are morphine, with or without scopolamine, the barbiturates and paraldehyde. No one drug is ideal, for a drug thus used must be safe not only for the mother but also for the baby and should have no effect on the progress of labor. Most of these drugs, when given in sufficient amounts to produce analgesia and/or amnesia, delay labor and cause fetal asphyxia.* This interference with the

normal process of labor often results in operative intervention, with increased hazards to mother and baby. The fetal asphyxia necessitates methods of resuscitation with increased fetal mortality. The use of paraldehyde has the same disadvantages.

URINARY INFECTION WITH STAPHYLOCOCCUS ALBUS

To the Editor:—A patient has a *Staphylococcus albus* urinary infection. She complains of frequency and a feeling of pressure over the bladder when she has to urinate. What antiseptic would you advise?

FREDERICK B. DEVITT, M.D., Oneonta, N. Y.

ANSWER.—In treating patients with *Staphylococcus albus* infection of the urinary tract, intravenous neosarsphenamine and the instillation of 30 cc. of 5 per cent mild protein silver in the bladder has been most helpful. Frequently there is an accompanying cicatricial urethritis in association with these cases, and dilation of the urethra plus the application of 5 per cent strong protein silver tampons to the urethra will often be worth while. It would also be helpful to eradicate any existing foci of infection.

WEANING

To the Editor:—What is considered the proper time and method to begin weaning a normal breast-fed baby? Both baby and mother are normal in every way and the supply of lactation is adequate. The baby is receiving the usual amounts of cod liver oil, orange juice, cereal, egg yolk and vegetables, at 6 months of age.

M.D., Illinois.

ANSWER.—The time for weaning a normal breast-fed baby varies with the condition of the baby and the mother. Usually weaning can commence at about the sixth or seventh month in a healthy baby of good weight. By this time the supplementary foods such as fruits and vegetables have probably been started and dentition should be well under way. The method for weaning should be gradual, one nursing at the breast being supplemented by a bottle feeding daily at the start. Then, after from ten days to two weeks, two daily bottle feedings may be substituted. After another interval three bottle feedings and two nursings are allowed. With such a gradual procedure in weaning, the milk supply in the mother's breast is slowly diminished so that by the time the infant is entirely weaned the mother should experience no difficulty in drying up the remainder of her milk supply.

ENNJAY SOLVENT NO. 2

To the Editor:—I should like information as to the toxicity of the metal cleaner known as Ennjay Solvent No. 2, made by the William J. Hough Company, Chicago. From an industrial point of view would it be considered as toxic as or more toxic to exposed workers than xylene?

M.D., Indiana.

ANSWER.—The William J. Hough Company market a metal cleaner under the designation of Ennjay Solvent No. 2, which, however, is believed to be manufactured by the Standard Oil Company of New Jersey. Without actual analysis, it appears that this cleaner's chief component is petroleum naphtha, of a grade akin to Stoddard's solvent. Tests were made for a chlorinated hydrocarbon content and no evidence of such was found. It appears that this cleaner may contain a low percentage of some coal tar derivative, possibly toluene or xylene. This, however, has not been demonstrated. On these assumptions, this cleaner may be regarded as less toxic than toluene under conditions providing equal exposure to the vapors of these individual substances. However, it is to be recognized that the vapors of petroleum naphtha are not entirely innocuous and on occasion have produced both acute and chronic episodes. More nearly exact data possibly may be obtained from the Standard Oil Company of New Jersey and certainly from fractional distillation, should circumstances warrant.

ROENTGEN THERAPY OF PITUITARY FOR MENORRHAGIA

To the Editor:—What is the present status of roentgen therapy over the pituitary gland as treatment for menorrhagia for which there is no demonstrable local cause? Are there any bad after-effects? M.D., Alabama.

ANSWER.—Irradiation of the pituitary gland with roentgen rays is usually employed in cases of menopausal disturbances and amenorrhea rather than for menorrhagia. In the hands of experienced roentgenologists practically no apparent harm has resulted from this form of therapy. However, in some young women an undesired permanent amenorrhea has followed such treatment. Of course during the menopause such a result is of no significance. Great caution must be exercised in the use of

roentgen treatment of the pituitary for any purpose, especially by roentgenologists not familiar with this form of therapy. In most cases of menorrhagia during the menopause, radium applied within the uterus or roentgen treatment over the uterus is safer than irradiation of the hypophysis. In young women conservative measures, including rest in bed, oxytocics, thyroid and sometimes other endocrine products, will usually suffice until normal conditions are restored. Of course in every case of severe and prolonged menorrhagia, especially at the change of life, a careful curettement should be performed to rule out the presence of carcinoma.

ETIOLOGY OF KALA-AZAR AND GRANULOMA INGUINALE

To the Editor:—What is the relationship between the etiologic agent of kala-azar, *Leishmania donovani*, and the so-called Donovan body, frequently described as the specific organism of granuloma inguinale? Are they both animal parasites? Some authorities refer to one as a protozoan, the other as a bacillus. What is regarded at present as the causative agent in granuloma inguinale?

IRVING M. CLYNE, M.D., Far Rockaway, N. Y.

ANSWER.—*Leishmania donovani*, of which the Leishman-Donovan body of kala-azar is the typical vertebrate phase, belongs to the hemoflagellates, which are classified by protozoologists as animal flagellates. There seems fair agreement that the Donovan body described in granuloma inguinale is not related to the Leishmanias and is probably not an animal organism, but there is considerable difference of opinion as to its exact nature. Many investigators believe that it is an encapsulated gram-negative bacillus (*B. granuloma* or *Klebsiella granulomatis*) related to Friedländer's bacillus. This, however, has not been definitely established and the recent work of Dienst, Greenblatt and Sanderson (*J. Infect. Dis.* 62:112, 1938) indicates that although the Donovan bodies are the etiologic agent of granuloma inguinale they are not related to the Friedländer type of bacilli since they were able to produce a typical lesion in a healthy volunteer by artificial inoculation with an exudate rich in Donovan bodies and free from culturable bacteria.

STERILIZING RUBBER GLOVES

To the Editor:—Please outline a practical method of sterilizing rubber gloves and packing them so that they will be sterile when used. I want information on a method that can be used by one who is practicing general medicine and doing obstetric work where an autoclave is not available.

M.D., Pennsylvania.

ANSWER.—In the absence of facilities for steam sterilization, the following procedure for the sterilization of rubber gloves is suggested:

Insert into the hand of the glove a pack of gauze or other porous material about one-fourth inch thick to hold the rubber surfaces apart. This pad should be inserted as far as the base of the fingers of the glove. Immerse the gloves in a pan of water and boil for at least thirty minutes. After boiling, remove the gloves, dry them with a sterile towel under aseptic technic and then fold them into a sterile towel until needed. Gloves sterilized in this fashion can be put on by immersing in sterile water and drawn on the submerged hand if sterile talcum is not available.

CALLAHAN TUBES IN DACRYOCYSTITIS

To the Editor:—In the *American Journal of Ophthalmology* (19: 601 [July] 1936) there is an article on the use of the Callahan tubes in chronic dacryocystitis. I should like to know the real scientific nature of this kind of treatment.

GUILLERMO ARAOS FRASER, M.D., Colombia, South America.

ANSWER.—The article referred to was written by Dr. C. N. Spratt, ophthalmologist of Minneapolis, and recorded the relief obtained in sixty-two of sixty-five cases of dacryostenosis by the use of the Callahan tubes. These are thin silver tubes that are introduced into the lacrimal passage and are open at both the upper and the lower end, the latter of which is located in the nose directly under the turbinate. The theory underlying the use of the Callahan tubes is perfectly sound, the purpose being to drain tears through a passage the patency of which is maintained by a foreign tube not subject to scar tissue constriction. The physiology of normal tear drainage is altered by the elimination of the pump action of the sac and of the effect of the ciliated epithelium. Therefore, only gravity remains. Practical objections to the use of the tubes may arise after more clinical experiences have been recorded, but at present the tubes would seem to offer a favorable solution to an intractable problem.

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the *National Board of Medical Examiners* and *Special Boards* were published in *THE JOURNAL*, August 13, page 647.

Arkansas June Examination

Dr. L. J. Kosminsky, secretary, State Medical Board of the Arkansas Medical Society, reports the written examination held at Little Rock, June 9-10, 1938. The examination covered twelve subjects. An average of 75 per cent was required to pass. Seventy-one candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine.....(1937)	(1938) 79.2, 79.8, 80.1, 80.3, 80.5, 80.8, 81.1, 81.9, 82.1, 82.3, 82.4, 82.4, 82.4, 82.8, 82.8, 82.9, 83.1, 83.1, 83.2, 83.3, 83.3, 83.4, 83.5, 83.8, 83.8, 83.8, 84, 84.1, 84.1, 84.3, 84.3, 84.3, 84.4, 84.5, 84.7, 84.8, 84.8, 84.8, 85, 85, 85.1, 85.2, 85.3, 85.3, 85.4, 85.7, 85.8, 85.8, 85.8, 85.8, 85.8, 86.1, 86.3, 86.3, 86.8, 87.1, 87.3, 87.3, 87.8, 88.4, 89.1, 89.2, 89.3, 90, 90.3, 91.3, 91.9	(1937)	85.3,
College of Physicians and Surgeons, Boston.....(1937)			87
Columbia University College of Physicians and Surgeons.(1935)			86.3

Ten physicians were licensed by reciprocity from January 12 through June 11. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Colorado School of Medicine....(1932), (1936)			Colorado
Johns Hopkins University School of Medicine.....(1937)			Maryland
Marion-Sims College of Medicine, Missouri.....(1896)			Oklahoma
St. Louis University School of Medicine.....(1932)			Missouri
Washington University School of Medicine.....(1934)			Missouri
Jefferson Medical College of Philadelphia.....(1932)			New Jersey
University of Tennessee College of Medicine.(1936, 2), (1937)			Tennessee

Maryland (Homeopathic) June Examination

Dr. John A. Evans, secretary, Board of (Homeopathic) Medical Examiners, reports the written examination held at Baltimore, June 21-22, 1938. The examination covered nine subjects and included seventy questions. An average of 75 per cent was required to pass. Thirty-one candidates were examined, thirty of whom passed and one failed. The following school was represented:

School	PASSED	Year Grad.	Per Cent
Hahnemann Medical College and Hospital Philadelphia..(1937)	84, 85, 86, 88, 89, 90, 90, 92, 92, 92, 92, 93, 94, (1938) 80, 82, 83, 83, 83, 84, 84, 85, 85, 86, 86, 86, 86, 87, 87	(1937)	80, 83,
School	FAILED	Year Grad.	Per Cent
Hahnemann Medical College and Hospital of Philadelphia.(1937)			74

Michigan Indorsement Report

Dr. J. Earl McIntyre, secretary, Michigan State Board of Registration in Medicine, reports fifty-eight physicians licensed by indorsement from Jan. 3 through July 27, 1938. The following schools were represented:

School	LICENSED BY INDORSEMENT	Year Grad.	Indorsement of
University of Arkansas School of Medicine.....(1935)			Arkansas
University of Colorado School of Medicine (1933), (1937, 2)			Colorado

Book Notices

Malaria in Europe: An Ecological Study. By L. W. Hackett, M.D., Dr.P.H., Assistant Director, International Health Division, Rockefeller Foundation. University of London, Heath Clark Lectures, 1934, Delivered at the London School of Hygiene and Tropical Medicine. Cloth, Price, \$3.75. Pp. 336, with 60 illustrations. New York & London: Oxford University Press, 1937.

This book is based on the Heath Clark lectures given at the London School of Tropical Medicine in 1934. It is the outgrowth of the work of the Malaria Experiment Station at Rome, now the Laboratory of Malaria Studies under the direction of Professor Missiroli of the new Italian Institute of Public Health. The author is assistant director of the International Health Division of the Rockefeller Foundation, which founded the Malaria Station in Rome in 1925 and carried on investigations on malaria in the Roman Campagna and at other centers in Greece, Bulgaria and Spain. Cooperation with other malariologists, especially Professor Martini at Hamburg and Professor Swellengrebel at Amsterdam, was utilized in the solution of problems of malaria and anophelism in the countries of northern Europe where anophelism both with and without malaria presented perplexing local and seasonal problems.

As the title indicates, the book is an ecologic study involving the interrelations of three interdependent groups of organisms, man, a series of related mosquitoes, and several species of Plasmodium, and these, moreover, in relation to man's domesticated animals. In its biologic aspects it is a superb demonstration of the specificities, complexities and deviations of the mutual adaptations which arise and become diversified in connection with the establishment of parasites in civilized social man. Its consequences ramify into human history as a factor in the decline of the civilizations of Greece and Rome or into human sociology when the absentee land owners of the large farms of the Roman Campagna were charged with creating conditions favoring malaria among the peasant population. It is admitted that famine and poverty affect the clinical manifestations of malaria and that improved economic conditions mitigate them, but the most prosperous communities suffer terribly at times. Social and economic uplift are no substitute for laborious antilarval campaigns and meticulous mosquito-proofing of houses.

The solution of the perplexing problem of anophelism without malaria in many European areas was solved when it was discovered that *Anopheles maculipennis*, the European vector of malaria, instead of being a single species in reality included no less than six distinct types, with constant characteristics such as egg markings, sexual behavior, breeding habits and zoophilic preferences. Two of the six preferred human blood, three fed by preference on cattle, and one on both. These preferences were determined by precipitin tests on the last blood meal of thousands of mosquitoes. Most of the zoophilic mosquitoes, even when captured in houses, were found to have fed on cattle. The part that the domestic animals of man play in the complicated picture of the distribution of mosquitoes and the incidence of malaria is a very important one.

Public health measures for the reduction of malarial mosquitoes seem to have swung away from drainage made popular by the successes of the engineers in the Canal Zone and to have turned more toward dusting the breeding waters of *Anopheles* by airplane with paris green and especially in recent years to the introduction of the top minnow, *Gambusia*, which feeds on the mosquito larvae but is seriously hampered by matted vegetation and running water and has seasonal limitations. An intimate knowledge of the habits and distribution of all local mosquitoes is essential to the economical and effective use of all methods of mosquito control. Truly the path of the public health officer charged with the obligation of reducing malaria is neither wide nor straight but devious and full of pitfalls. It requires an adaptation to local circumstances and an opportunism beyond that required by any other major disease of man. This arises from the fact that the mosquito lives in two habitats, the water and the air, in which it can infest large areas and all abodes of man.

The use of quinine in the treatment of malaria has had a vogue of 300 years but there is still no uniformity as to the

mode of treatment and still less agreement as to its action and efficiency. The use of malaria in the treatment of dementia paralytica has proved that quinine does not kill sporozoites injected by the mosquito and so cannot prevent an infection. Some clinical reaction on the part of the infected host seems to be necessary to render it effective, possibly in the activation of an immune mechanism. Neither can quinine sterilize the sexual forms, at least of *Plasmodium falciparum*. No intensification of treatment will result in the radical cure of more than a certain percentage of infected persons. It seems even to check growing immunity in some cases.

The new synthetic atabrine and plasmochin have promise of replacing quinine. The former has none of the ill effects known as cinchonism and seems to be followed by fewer relapses but may cause mental derangement. Plasmochin in minute quantities sterilizes the sexual forms of all species of *Plasmodium* in the blood and therefore is of great importance in eliminating these sources of the infection of mosquitoes in the human population in malarial districts, but it has no prophylactic value and its therapeutic utility is contested.

This book cannot be reviewed adequately. It is a mine of detailed information in an immense field of recent research of great importance in the prevention and control of malaria and of medical practice in malarial regions. As a biologic document in the new and important field of animal ecology it is unsurpassed as a revelation of the intricate interrelations of organisms associated in the complex of parasitism. It is a book to be read, reread and read again as a superb piece of constructive, scientific medicine. Its greatest service to the medical profession and to the public interested in the sound progress of public health measures lies in its lucid and complete demonstration of the complicated nature of at least this one problem of public health. Its solution requires adequately trained technical personnel and their cooperation over a large area and for a long time, but its results bid fair to be of lasting value.

Introduction à la chirurgie digestive. Par E. E. Lauwers. Préface du P^r P. Duval. Paper. Price, 38 francs. Pp. 223. Paris: Masson & Cie, 1937.

This essay is one of the links in a chain of five introductions by the same author to various fields of surgery, the others being introduction to surgery of the nervous system, reconstructive, thoracic and genito-urinary surgery; it brings before the eyes of the reader the general problems of this special field by making excursions into the realms of diagnosis, therapeutics and technic. The noted surgeon Pierre Duval states in the preface that three periods may be distinguished in the surgery of the digestive tract: During the first an immediate success was the main goal of the surgeon; to attain it, more and more audacious procedures were devised. The second period was characterized by improvements in the technic for the purpose of restitution of anatomic perfection. During the present, or third period, attempts are being made to combine the anatomic with functional perfection; to accomplish this and to avoid so-called operative malady caused by anatomic mutilations, a profound knowledge of normal anatomy, normal and pathologic physiology, organic chemistry, and general and organic biology is necessary. These fundamental informations, necessary for a comprehension of the surgical pathology of the digestive tract and for judicious surgery, form the base of this work. After a brief review of embryonal development of the abdominal organs the author describes malformations of the peritoneum and intestinal canal and touches on the physiology of this region. Surgical anatomy of hernias and clinical and laboratory diagnostic methods form the subject of the following chapters. Others deal with peritonitis, traumas of the abdominal region, ileus, peptic ulcers, diverticula and other important surgical conditions of the gastrointestinal tract. The closing chapters treat of surgery of the liver, biliary tract, pancreas and spleen. With admirable erudition the author picked up the high points of physiology, surgical anatomy, diagnosis and treatment of the most important pathologic conditions; he may be congratulated on his masterful, concise presentation of the subject. The book deserves translation into English to make it more accessible to the American surgeon who does not read French.

Illness: Its Story and Some Common Symptoms. A Guide for the Layman. By S. Henning Belfrage, M.D. Cloth. Price, \$1.50. Pp. 175. New York & London: Oxford University Press, 1938.

This little volume, measuring 4 by 6 inches and less than five-eighths inch in thickness exclusive of the covers, is an effort to condense too much into too little space. Four pages is devoted to a foreword, five pages to "The Attainment of Health," three pages to "The Meaning of Symptoms," eight pages to "The Causes of Disease" and eleven pages to "The Nature of Disease." Merely to list the headings and the amount of space devoted to their discussion is to expose the inadequacy of this section of the book. In part two are listed "Some Common Symptoms. Their Origin, Significance, and First-Aid Treatment." Each of these symptoms is treated in a brief paragraph which is superficial and in many instances inaccurate. While the book contains much useful information, it usually falls far short of adequate treatment, even of symptoms. Fundamentally the whole idea of giving lay persons a list of symptoms and advice as to what to do about them is unsound. Such information as that contained under the heading of "Back Ache" is distinctly false. For example, "The attack tends to pass off with rest, the application of heat to the inflamed muscle, deep massage and mild purge, and five to ten grains of aspirin repeated every four to six hours if pain is severe." The book cannot be recommended.

Probleme der Biologie. Herausgegeben von Erich Ries und Karl Wetzel. Band 1: Hormone bei wirbellosen Tieren. Von Gottfried Koller, a. o. Professor der Universität Kiel z. Zt. Ordinarius für Zoologie an der Staatlichen Tung Chi-Universität in Shanghai-Woosung. Cloth. Price, 10.80 marks. Pp. 143, with 27 illustrations. Leipzig: Akademische Verlagsgesellschaft m. b. H., 1938.

This volume is well written and adequately illustrates work on the physiology of the hormones of certain invertebrate animals. The author has condensed his study of these hormones into four primary divisions. One section is devoted to a consideration of cellular hormones: those elaborated by a cell and effective within the same unicellular organism. In another section are considered hormones of aglandular tissue, wherein the heart-stimulating regulators and neural hormones are discussed. A third section is devoted to the glandular hormones, such as sex hormones, hormones regulating metamorphosis and those controlling changes of color of the integument. A concluding section of the volume covers the literature relative to the effect of mammalian hormones on certain representative animals of the invertebrate phyla. The effects of the administration of hormones of the thyroid, pituitary and adrenal glands are discussed. An extensive bibliography is appended. This volume represents a distinct contribution to knowledge of endocrinology of invertebrates but clearly is not of practical significance to the busy physician in diagnosing disarrangements in the function of the endocrine system in man.

The Measurement of Outcomes of Physical Education for College Women. By Elizabeth Graybeal, Director of Physical Education for Women, State Teachers College, Duluth, Minnesota. Paper. Price, \$1. Pp. 80, with 9 illustrations. Minneapolis: University of Minnesota Press, 1937.

This is an extensive and detailed report of studies at the University of Minnesota of the outcome of physical education for women. An effort is made to express gain or loss in attitudes, knowledge, motor ability and posture on a percentage basis down to the second decimal place. Differentiation is made between groups with little activity and groups with much activity. The conclusion is arrived at that gains in attitude, knowledge, motor ability and posture attributable to supervised activity in physical education are in excess of gains attributable to unsupervised activity. Motor ability tests known as the Minnesota Graybeal tests are described and tests of them are published. Measurements of growth in physical education are made, including gains in information or knowledge, in which a gain of 68 per cent was made by the experimental group and only 9.4 per cent by the control group. In motor ability the experimental group gained 7 per cent while the control group gained 10 per cent. In posture the experimental group gained 25 per cent while the control group gained 23 per cent, indicating, of course, no appreciable difference. The study should be of great interest to physical educators. To the medical reviewer it looks very much as if the summary and conclusions, so laboriously arrived

at, could have been pretty much predicted on the basis of general information and experience. The expression of percentages to the second decimal place in measuring such variable and subjective qualities as attitudes, knowledge, motor ability and posture gives a fictitious appearance of accuracy.

Sepsis nach Angina. Von Prof. Dr. W. Uffenorde und Prof. Dr. H. Claus. Heft 1, Hals-, Nasen- und Ohrenheilkunde, zwanglose Schriftenreihe. Herausgegeben von Prof. Dr. H. Loebell und Prof. Dr. W. Tonnendorf. Second edition. Paper. Price, 4.50 marks. Pp. 37, with one illustration. Leipzig: Curt Kabitzsch, 1938.

As early as 1920 Mosher in this country called the attention of physicians to the septicemia which follows acute pharyngeal infections and which is due often to involvement of the jugular vein, secondary usually in his experience to deep cervical collections of pus. Some years later in Austria and Germany this topic aroused great interest. In Berlin a special pavilion was established in recognition of the fact that many obscure cases of septicemia arose from tonsillar infections. These, moreover, may have been mild and present some weeks before. The relationship between the severe present illness and the perhaps forgotten tonsillitis of sometime before was often not recognized. There remains considerable controversy as to the origin of septicemias from tonsillar infections. These are brought about, it is agreed, in more than one way. Rapidly fatal forms occur, usually by direct invasion of the blood stream by way of the retrotonsillar veins and without thrombophlebitic changes. More often thrombophlebitis of the retrotonsillar veins is present with possible extension as far as the internal jugular vein. Less directly, the veins may be attacked by inflammations involving lymph nodes in close contact with them or by being bathed in the pus of phlegmons arising in the interfascial spaces of the neck. These arise by direct extension from peritonsillar abscesses or secondarily by way of lymphadenitic and thrombophlebitic processes. Therapy consists of removal of the involved tonsils, drainage of cervical abscesses and ligation of the thrombosed jugular vein; in addition, use of sulfanilamide and blood transfusions are considered useful. Most of these things the authors stress. They are pioneers in investigations of this type of disease and they have added greatly to its recognition and proper therapy. The specialist and general practitioner need to be aware of the information this work brings, to the end that many needless deaths from obscure sepsis may be prevented.

Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern. Methodik der Röntgenuntersuchung des Kehlkopfes. Von Dr. Richard Waldapfel, Assistent der Ohren-, Nasen-, Halsabteilung der allgemeinen Poliklinik in Wien. Fortschritte auf dem Gebiete der Röntgenstrahlen, Ergänzungsband LIII. Herausgeber: Prof. Grashy. Paper. Price, 17.60 marks. Pp. 91, with 77 illustrations. Leipzig: Georg Thieme, 1938.

The first attempts to examine the larynx roentgenologically were made at the beginning of this century. First the position of the vocal cords was studied by Scheier. Later on Thost presented the diseases of the larynx and its neighboring organs in a special atlas. The new textbook of Waldapfel deals with the same area taken from the rich material of the Clinic Hajek, Vienna. In addition to the transverse and anteroposterior exposure Waldapfel makes use of the placement of a film in the retropharyngeal space. A film specially cut is introduced into the retropharyngeal space as far as the beginning of the esophagus after anesthetization of the posterior wall of the retropharynx and is held by a forceps. Exposure is taken by the experiment of Valsalva to increase the contrast between the air and the soft tissues. Furthermore, the examination of Fossion is recommended. The larynx is moved forward. By means of air inflation in the retropharyngeal space it is possible to visualize the retrolaryngeal and hypopharyngeal space also and to discover the involvements in the posterior portions of the larynx in their full extent. The author points out the objects of x-ray examination of the larynx as follows: outlines and extent of laryngeal processes; narrowing of the air space; size and extent of stenosis; extent of involvements in front and behind the larynx, and thickening and destruction of cartilaginous parts of the larynx. Numerous instructive roentgenograms and sketches with interpretations make the results of examination understandable to every laryngologist. Here we are dealing with a supplementary examination; all the other clinical examinations have to be done in advance.

A Text-Book of Pharmaceutics. By Arthur Owen Bentley, Reader in Pharmaceutics and Head of the School of Pharmacy in the University College of Nottingham, and others. Fourth edition. Cloth. Price, \$5. Pp. 1,001, with 234 illustrations. Baltimore: William Wood & Company, 1937.

This is a book on the practice of pharmacy in accordance with the Addendum (1936) to the British Pharmacopoeia and the British Pharmaceutical Codex of 1934; and it incorporates, as the author states, the recent advances in pharmaceutical education as is evidenced by such chapters as the ones on osmotic pressure, isotonic solutions, electrolysis and hydrogen ion concentration, absorption, viscosity determinations, the colloidal state, and the theory of emulsions. The first part of the book discusses the political history of pharmacy in Great Britain. Part 2 takes up general principles and apparatus; part 3, dispensing; part 4, pharmaceutical preparations. In part 5, under the heading of pharmaceutical biology, are taken up the matters of bacteriology, sterilization, preparation of solutions for parenteral administration, vaccines and serums. Part 6 discusses briefly the principle of biologic assay of pharmaceutical preparations. There are a good many items in this book that might with advantage be incorporated in the current pharmaceutical education in this country; and for this reason the book is recommended to pharmaceutical libraries, teachers of pharmacy and practicing pharmacists who wish to keep abreast with the trend of pharmaceutical progress in the British Empire.

Father's Doing Nicely: The Expectant Father's Handbook. By David Victor. With a foreword by George W. Kosmak, M.D. Cloth. Price, \$1.50. Pp. 170, with illustrations by Tom Torre Bevens. Indianapolis & New York: Bobbs-Merrill Company, 1938.

The glory of motherhood and the role of the mother in child-bearing have been rightfully extolled. The role of the father, however, has received but scant attention. The problems of reproduction must be shared by both mother and father. Although many books have been written about motherhood, this small book presents the problems of the father. The birth of a baby in the average American household is still the most important and exciting event in the lifetime of that household. It calls for tremendous physical, environmental and economic adjustment. The peace and welfare of a family may be seriously jeopardized. Failure of adjustment to the new situation may result in irreparable damage to the family. Any information which helps to make this transition easier and more natural renders a distinct service. The author discusses the many problems involved in the birth of a baby in an amusing and yet instructive manner. Thus, the father is gently led over such hurdles as the economics of childbearing, the trials and tribulations of labor, and the environmental adjustment in the home. The father is made to feel that he is a true partner in the present and future of the new heir or heiress. The book can be heartily recommended to expectant fathers.

La maladie de Lobstein: Le syndrome des sclérotiques bleues dans ses rapports avec la fragilité osseuse et l'hérédosyphilis. Par Georges Carrière, professeur de clinique médicale, Claude Huriez, professeur agrégé à la Faculté de médecine de l'Université de Lille, et William Hocq. Paper. Pp. 163, with 29 illustrations. Paris: G. Doin & Cie, 1938.

This is a monograph on the syndrome of blue sclerotics with osteopsathyrosis, or fragilitas ossium, called Lobstein's disease after Lobstein's report in 1933. The authors divide the ocular syndrome with blue sclerotics into (1) the osseous syndrome with psathyrotic deformities and developmental changes of bone; (2) the articular syndrome, namely deafness; (3) the articular syndrome, and (4) the endocrine syndrome. The most constant observations are the blue sclerotics, which are of diagnostic significance if they are familial and associated with auditory symptoms. The authors distinguish between complete and incomplete forms of Lobstein's disease. In discussing the osseous symptoms they mention also the vertical form of osteopsathyrosis. The craniofacial deformations are particularly frequent; the occluding temporal and frontal bones, the smallness of the face and the skull, the thinning of the cranial wall. The articular syndrome is merely excessive relaxation of the joints, which is inconstant. The articular syndrome is particularly otosclerosis. Much space is devoted to the endocrine aspects. The authors mention various deficiencies but particularly the

dysfunction of the parathyroids. They point to the frequent finding of hypocalcemia and regard it rational to consider the removal of the parathyroid. This was done in two patients; while it is too early to report definitely, there have been no successive fractures, the calcemia being at normal level. The authors state that in the great majority of cases the disease, which is hereditary or familial, shows hereditary stigmas such as high infant mortality, frequency of osseous malformation and dental changes of hereditary aspect, frequent polyglandular syndromes, and finally the articular and auricular symptoms which are, according to the authors, similar to those of tabes. While it must be admitted that the pathogenic background of this disease is little documented, the book is to be recommended as a scientific and thorough treatise on this disease.

Ophthalmoskopische Studien in monochromatischem, sukzessiv veränderlichem Licht. I. Der normale Augenhintergrund. Von Ingemar Kugelberg, Med. Lic. Inauguraldissertation welche mit gehöriger Genehmigung der weiterführenden medizinischen Fakultät zu Uppsala verteidigt wird. Paper. Pp. 183, with 7 illustrations. Uppsala: Almqvist & Wiksells, 1937.

Kugelberg has exhausted the study of the possible investigative methods with the instrument available in a review of the conditions found in the normal fundus with monochromatic light. His monochromatic apparatus consists of an Abbe prism of constant diversion which outlines a spectrum by means of the illuminous slit from an arc light which is intersected by a second slit providing a desired wavelength. By turning the prism one obtains successive wavelengths, which on account of the fluctuating dispersion and intensity may be corrected by the change in size of the slit. The apparatus is checked for measurement of wavelength by means of a linear spectrum and thereby the consistency of the monochromatic nature of the wave is assured. The pamphlet is divided into ten chapters, on (1) introductory matter and survey, (2) method, (3) survey of the normal background of the eye in monochromatic light, (4) the retinal arteries, (5) the retinal veins, (6) the choroidal vessels, (7) the reflex of the retinal vessels, (8) the diffusion of light in the choroid, (9) the reflection on the internal limiting membrane and the striped structures of the nerve fiber layers, and (10) the question of the macula. A good summary of the work is incorporated in the final six pages of the pamphlet. Pertinent references fill another six pages. The material constitutes a comprehensive review and experimental insight into this limited field of endeavor. The author intends to continue with an anatomicohistologic study to verify his results.

Pharmaceutical Therapeutics with Pharmacology, Posology and Toxicology. By Eldin V. Lynn, Ph.D., Professor of Chemistry, Massachusetts College of Pharmacy, Boston. Second edition. Cloth. Price, \$4. Pp. 430. New York & London: McGraw-Hill Book Company, Inc., 1938.

The object of this book is to present for students and practitioners of pharmacy the essential facts of pharmacology, toxicology and therapeutics of all drugs appearing in the United States Pharmacopeia, the National Formulary and New and Nonofficial Remedies (unfortunately abbreviated throughout as N. R. instead of N. N. R.); a few drugs not appearing in any of these publications are also included. The task is accomplished most admirably, and it would seem that in its new edition this work would be practically indispensable to the pharmacist studiously interested in the practice of his venerable and important profession.

Die endokrinen Erkrankungen: Ihre Klinik, Pathologie und Therapie. Von Prof. Dr. N. v. Jagić, Vorstand der zweiten medizinischen Universitätsklinik, Wien, und Doz. Dr. K. Fellinger, Vorstand der Intern. u. Stoffw.-Abt. am Krankenhaus der Stadt Wien. Paper. Price, 9 marks. Pp. 293, with 37 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1938.

This book is intended to aid the physician in finding his way through the maze of endocrine diagnosis and in separating the valuable from the worthless endocrine remedies. The authors present a fairly critical summary of endocrine diseases; but the glandular preparations recommended, or suggested for trial, include many of dubious potency and a few for which there is no excuse. Even though no great enthusiasm is shown for these products, they would better have been omitted or properly classified.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Taxes: Liability of Optometrist for Retailers' Occupation Tax.—The Illinois Retailers' Occupation Tax Act imposes a tax on the seller of tangible personal property at retail. The State Department of Finance promulgated a rule under the act to the effect that "if optometrists or oculists also act as opticians, or sell spectacles, eyeglasses, lenses, frames, or other tangible personal property to users or consumers, they incur liability for tax with respect to receipts from such sales." The plaintiffs, optometrists, instituted a suit to restrain the collection of the tax sought to be imposed on them. The trial court entered a decree for the defendants; the Director of Finance and the Attorney General, and the plaintiffs appealed to the Supreme Court of Illinois.

The sole question before the court was whether the fact that in the carrying on of the practice of optometry the person receiving the service, if called on to purchase eyeglasses, frames or other tangibles from the optometrist, participates in a sale of tangibles which is taxable under the Retailers' Occupation Tax Act. If, said the court, it becomes necessary for a physician to furnish medicine or surgical dressings in effecting a cure, he certainly does not thereby come within the designation of those engaged in a calling which would result in the imposition of a retail tax. The same reasoning applies to dentists even though that calling requires the furnishing of certain inlays, fills or crowns, or even false teeth, if necessary to a completion of the dental service. The exemption of these two professions from the operation of the act was recognized by a special rule promulgated by the Department of Finance. The main object and purpose of optometry, in the opinion of the court, is to furnish service to one requiring a correction of vision. It is not a craft or a trade, but a personal professional calling in which a reputation is built up because of the efficiency of the service rendered. The requirements of the optometry practice act insist on a good moral character on the part of an applicant for a license, graduation from an approved school of optometry, and the passing of satisfactory examinations and tests as to educational fitness. Not one of these requisites is necessary for one engaged in the business of the retail sales of tangibles.

In the opinion of the court the legislature, in providing for the licensing of optometrists, created a calling distinct in its character from that of the retailer who sells similar tangibles in the pursuit of a trade, and the optometrist engaged solely in his professional occupation is not subject to the tax. The decree of the trial court was therefore reversed and the case remanded with directions.—*Babcock v. Nudelman (Ill.)*, 12 N. E. (2d) 635.

Compensation of Physicians: Liability of Father for Medical Services Rendered to Adult Son.—The defendant's adult son was critically injured and was immediately taken to a hospital. The defendant hurried to the hospital and after considering the advisability of obtaining the services of two other physicians he finally authorized the chief surgeon of the hospital to operate on the son, telling him to do all that he could for the patient and to spare no expense. On being told that a special night nurse was needed, the father authorized the surgeon to get one and reiterated the statement to spare no expense. A day nurse was employed, as was also a physician to assist in the operation. Thereafter the father refused to pay the expense incurred in the treatment of his son, and the hospital, the chief surgeon, the assistant physician and the two nurses instituted separate actions against the father. By agreement, the cases were tried together. The trial court gave judgment in each case against the defendant, who thereupon appealed to the Supreme Court of South Carolina, denying liability on the ground that he had made no contract to pay for the services.

As a rule, said the Supreme Court, a request by a parent to a physician to attend an adult child does not create an implied

contract on the part of the parent to pay for the services rendered by the physician. This rule, however, is not of invariable application, for the conditions and circumstances surrounding the parties at the time the request is made, as well as the utterances on the subject, must be taken into consideration. If, under the facts and circumstances, the physician is justified in believing and relying on the parents' intention to pay for the services rendered, although there is no express promise to pay therefor, an implied contract to pay is created. If there is nothing in the facts and circumstances suggesting to the physician that the parent intends to assume the legal obligation to pay, at the time the request for services is made, the parent is no more legally liable for services rendered to his adult child, living away from his home, than he would be for services requested to be rendered to a total stranger. There was no express contract in the present case but the court was of the opinion that the surrounding circumstances were such as to create an implied contract. When the father arrived at the hospital, he was advised that he could employ any surgeon he preferred to perform the necessary surgical operation. The father selected the chief surgeon, telling him to do everything possible for his wounded son and to spare no expense. If the statement made by the defendant had related to a stranger or a mere acquaintance, no liability would have been established. But here, the court pointed out, a father, on being advised of his wounded son's condition, came a long distance after night, and on finding his own flesh and blood in a critical condition, asked about other physicians and then, after conferring with other persons present, authorized the chief surgeon to proceed with the operation and to spare no expense. Such evidence, the court said, was sufficient to justify the trial court in submitting the issue to the jury as to whether or not an implied contract existed.

The defendant further contended that he was not liable for the services rendered by the day nurse, because the agency of the chief surgeon to employ her was proved only by his statements, which were insufficient to establish the agency. While it is true, the court said, that the declarations of an agent alone as to his agency are insufficient to prove the agency, it is also well established that if there are other corroborating facts and circumstances disclosed by the testimony, the existence of the agency then becomes a question for the jury. The court could find no error in the submission of this question to the jury.

The judgments in favor of the individual plaintiffs were affirmed.—*Broadway v. Jeffers, and four other cases (S. C.)*, 194 S. E. 642.

Workmen's Compensation Acts: Employer's Liability for Expense of Hospitalization Beyond Statutory Limits.—The defendant company sent one of its injured employees to the plaintiff hospital for treatment. The services rendered by the hospital extended from July 25, 1931, to June 18, 1932. Apparently, the hospital entered the charge for the services against the employer's insurer and from time to time sent bills to the insurer but received no payment. Eventually the insurer went into bankruptcy, and the hospital thereafter sought to collect from the defendant company. Finally suit was instituted and the trial court gave judgment for the hospital. The defendant company appealed to the Supreme Court of Wisconsin, contending, among other things, that it was not liable because of the fact that the hospital did not extend credit to it but to the insurer.

Liability for the expenses incident to hospitalization, the court said, does not depend on to whom credit was extended but on who in law was responsible for the payment of the bill. The employee himself was doubtless responsible for payment. The defendant company was also responsible for its payment because the workmen's compensation act made it responsible. The insurance company was also responsible for its payment because of its policy of indemnity to the defendant. That the hospital and the defendant company both considered the case as a compensation case was plain. This being so, the defendant was in effect a surety for the employee, and the insurance company was a surety for the defendant and therefore for the employee. The liability of the defendant was not affected, the court said, because it procured indemnity insurance or because the plaintiff sought payment from the defendant's surety and failed to recover

because of the surety company's bankruptcy. Where the relation of principal and surety exists, efforts to collect from a surety that fail do not relieve the principal.

The defendant further contended that, even if it was under contractual obligation to pay for the employee's hospitalization, its obligation was limited under the workmen's compensation act to hospitalization for ninety days. The act, however, the court pointed out, does not limit the obligation to ninety days but provides for liability beyond that period if in the opinion of the industrial commission further hospitalization will tend to lessen the period of compensable disability. The liability of the defendant for the expenses incident to hospitalization continued until such time as it was terminated by objection by the defendant to further hospitalization at its expense. No such objection was interposed in the present case. Liability would extend for at least a reasonable time, and there was no contention that hospitalization was unreasonably extended or unreasonably furnished in this case. The court was of the opinion therefore that, in absence of any objection by the defendant to hospitalization furnished, the defendant was properly adjudged liable for the amount allowed by the trial court.

The judgment of the trial court for the hospital was therefore affirmed.—*St. Mary's Hospital & Training School for Nurses of Sisters of Misericordia v. Atlas Warehouse and Cold Storage Co. (Wis.)*, 277 N. W. 144.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American J. Digestive Diseases, Huntington, Ind.

5: 281-344 (July) 1938

- Comparison of Streptococci from the Colon with Barger's Organism. J. F. Kessel, Los Angeles.—p. 281.
- IV. Experimental Study of Hydrogen Ion Concentration and Chemistry of Bile, Its Effect on Stones and a Suggestion as to Therapeutic Application of Ox Bile in Gallbladder Disease. S. Morrison, M. Feldman, J. C. Krantz Jr. and Frances F. Beck, Baltimore.—p. 288.
- Effect of Estrogenic Hormone on Gastric Acidity. L. Schiff and H. Felson, with technical assistance of Jane Graff and Betty Meyer, Cincinnati.—p. 292.
- *Migraine; Epilepsy: Their Association with Hypothyroidism. A. I. Rubenstone, Philadelphia.—p. 295.
- Phenolphthalein. H. W. Soper, St. Louis.—p. 297.
- Study of Diseases in the Negro, with Particular Reference to the Gastro-intestinal Tract. I. C. Sharon, Cincinnati.—p. 298.
- Practical Method for Determining Concentration of Buffer Salts in the Body Fluids. A. W. Oelgoetz, Columbus, Ohio.—p. 311.
- Terminal Ileitis: Conservative Surgical Treatment. I. Kross, New York.—p. 313.
- Karaya Gum as Mechanical Laxative: Experimental Study on Animals and Man. A. C. Ivy and Bertha L. Isaacs, Chicago.—p. 315.
- Intussusception in the Adult. R. Finkelstein, Brooklyn.—p. 322.

Migraine, Epilepsy and Hypothyroidism.—Rubenstone describes a woman with migraine and epilepsy whose two daughters were subject to migraine, one with the abdominal type and the other the cephalic. Hypothyroidism without the picture of myxedema was found in all three. They promptly responded to thyroid replacement therapy. Of the many theories regarding etiology, the most plausible is inherited allergic susceptibility with superimposed exciting causes, endocrine imbalance being the most prominent. The frequent low metabolic readings are significant of lowered thyroid function. The symptomatic relief produced by ergotamine tartrate may be due to its suddenly boosting endocrine function. For the recognition of the hypothyroid state it is important that basal metabolic readings be made as near as possible to an approaching attack and never immediately after.

American Journal of Physiology, Baltimore

123: 1-280 (July) 1938

- Experimental Renal Hypertension and Adrenalectomy. D. A. Collins, Minneapolis, and E. H. Wood, Philadelphia.—p. 224.
- Nitrogen Excretion on Nitrogen Free Diet. W. H. Seegers, Yellow Springs, Ohio.—p. 233.
- Experimental Production of Ovulation, Luteinization and Cysts of Corpus Luteum in Adrenalectomized Anestrous Cats. H. B. Friedgood and M. A. Foster, Boston.—p. 237.
- *Observations on Blood Sugar Level Before, During and After Hunger Periods in Humans. W. W. Scott, C. C. Scott and A. B. Luckhardt, Chicago.—p. 243.
- Effect of Alcohol on Hunger Sense. C. C. Scott, W. W. Scott and A. B. Luckhardt, Chicago.—p. 248.
- Effect of Calcium on Output of Sympathin in the Frog's Heart. K. Lissák, Boston.—p. 256.
- Excretion of Endogenous "Creatinine" by the Human Kidney. T. Findley Jr., St. Louis.—p. 260.
- Effect of Combined Thyroidectomy and Gonadectomy on Compensatory Adrenal Hypertrophy in Unilaterally Adrenalectomized Rats. Isolde T. Zeckwer, Philadelphia.—p. 266.
- Utilization of β Hydroxybutyric Acid by Isolated Mammalian Heart and Lungs. R. H. Barnes, La Jolla, Calif., E. M. MacKay, San Diego, Calif., G. K. Moe, and M. B. Visscher, Minneapolis.—p. 272.

Blood Sugar Level and Hunger.—The Scotts and Luckhardt find that the level of the blood sugar of the fasting human subject remains constant at the time the empty stomach is undergoing changes in activity. If there was any causal relationship between this level and hunger contractions this would not be the case. If a causal relationship existed, there should be a fall (or rise) in the level of the blood sugar preceding the

onset of the contractions and a subsequent rise (or fall) in the level after the contractions had ceased. This order of events would have to repeat itself before each succeeding hunger period. No evidence could be found for these hypotheses.

- Studies on Intranasal Preventive Treatment of Poliomyelitis. M. C. Myerson, New York.—p. 531.

Bronchiectasis and Sinus Infection.—Goodale studied the part that sinus infection played in seventy-five cases of bronchiectasis. According to x-ray evidence, forty-six patients now have chronic sinus infection and twenty-nine have negative sinuses. Of the twenty-nine negative cases, eighteen have a history or clinical evidence suggestive of sinusitis, either a recurrent acute sinusitis or a mild chronic sinusitis. In eleven cases (14.5 per cent) sinusitis seems to have had no part in the onset or subsequent course of the bronchiectasis. There seem to be several different diseases which can cause bronchiectasis. The largest group is that of infections of the upper part of the respiratory tract. Pneumonia alone accounts for twenty-one cases. These cases show a marked susceptibility to severe infection of the upper part of the respiratory tract. As time goes on these repeated infections have produced the picture of sinus disease which is greater than the etiology would indicate. It is found that the prevalence of sinus infection parallels the extent of the bronchiectasis. Reduced to percentages, the sinuses are infected in 40.7 per cent of those cases in which only one lobe is involved and in 73 per cent of cases in which more than one lobe is involved. Once the patient has acquired a chronic sinusitis, the chance of further damage to the lungs is increased because these patients are more susceptible to repeated infections of the respiratory tract.

- *Survey of Syphilis Among Students at University of Wisconsin. L. R. Cole, Madison, Wis.—p. 70.

Albuminuria and Scabies.—Niles examined the urine of 216 patients with scabies, most of whom were from the lower economic level. Their ages ranged from 19 months to 78 years. In order to eliminate the possibility of renal damage from the medication prescribed, the urine almost always was examined at the time of the first visit. Only sixteen patients showed even the slightest trace of albumin in the urine on one examination. The average age of patients of both sexes who showed

albuminuria was 6.5 years less than that of the whole group of patients with scabies. The average duration of scabies in the patients with albuminuria was 1.9 months in the entire series. This does not support the contention of some authors that albuminuria is more frequent with neglected scabies of long duration. None of the 216 patients had casts. Six patients showed varying amounts of sugar, twenty indican and twenty-seven pus cells. Of the seven patients who returned for reexamination, four failed to show albumin after the disappearance of the scabies, but in the other three albuminuria persisted for many months after the eruption had disappeared. In the three patients whose albuminuria continued after the disappearance of the scabies there probably was no relation between the two conditions, although they may furnish examples of the rare complication described by some authors as persistent albuminuria following scabies. The incidence of 7.4 per cent of albuminuria on one examination of the 216 patients suffering from scabies is not necessarily of any significance, as it is no higher than the percentage found in some reports of routine urinalyses of normal subjects.

Syphilis Among University Students.—Cole states that a total of 3,389 tests was done on 30.5 per cent of the student population of the University of Wisconsin. In two cases persistent 1 plus reactions and in one case a 2 plus reaction were found. The two patients with 1 plus reactions were women and the 2 plus reaction was that of a man from rural Wisconsin. Two men from urban centers in Wisconsin were discovered to have 4 plus reactions. These patients reported to the department of student health and were referred to private physicians for treatment. Six doubtful reactions were reported but the subjects never showed anything more than doubtful reactions. A legitimate criticism that the student with known syphilis will not report in a voluntary program of this type may be raised. Syphilis, however, seems to be extremely rare. Of approximately 2,000 admissions to the infirmary and approximately 50,000 outpatient visits during any year, only one or two cases of syphilis were discovered. Wassermann tests should be performed as a routine on each newly entering student and on each graduating student.

Chronic Appendicitis.—In an attempt to determine whether or not there is such a clinical entity as chronic appendicitis, Shelley compared the pathologic changes in appendixes believed either before or after removal to have been the cause of symptoms with the changes in those which apparently had never been the cause of symptoms. He determined the incidence of pathologic changes in appendixes supposed to have been the cause of symptoms according to symptoms, physical and laboratory observations, sex and age. The percentages of the patients followed up who remained free from symptoms was computed according to the pathologic change found in the appendix. A chronic inflammatory process, adhesions, fecaliths or combinations of these conditions in the appendix have been shown to be the cause of definite symptoms and physical changes which can be relieved by appendectomy. A general term "chronic

appendicitis" is suggested to cover these conditions. In properly selected cases an appendectomy for chronic appendicitis gives an excellent expectation of cure, but the following points should be considered: 1. In the presence of a history of nausea and vomiting or of constipation, especially in women, particular care must be exercised in the selection of cases. 2. The more definite and localized the physical changes, the better is the expectation of cure. When tenderness is found in other parts of the abdomen than the lower part of the right quadrant, one should be most reluctant to attribute the patient's symptoms to chronic appendicitis. 3. The expectation of cure is excellent when there is a history of more than one attack within a period of one year or less, much poorer when the attacks cover a period longer than one year and poorest when the patient is operated on in or following the first attack. When no inflammatory change is found in the appendix, the expectation of cure is not good unless either adhesions or fecaliths are present, in which case the results are nearly equal to those obtained when inflammatory changes are present. Owing to recurrent attacks, there is evidently an increase in the pathologic condition in the appendix, as the change with age is much more marked than in the absence of symptoms attributable to the appendix. When a patient has been operated on because of symptoms and physical signs diagnostic of acute or subacute appendicitis and, instead, one of the types of chronic appendicitis (or adhesions or fecaliths without inflammation) is found, the expectation of a permanent cure is excellent.

Pilonidal Sinus.—Block and Greene discuss four years of experience with the use of a sclerosing solution in the treatment of pilonidal sinus. The sclerosing method was employed in eleven cases of pilonidal sinus, whether the condition was acute or chronic and whether it was simple or complicated. In two or three days after an initial simple incision of the sinus, the sclerosing treatment is instituted. The pack is removed carefully and gently; the table is tilted so as to lower the upper half of the body to an angle of about 66 degrees, and the wound is completely filled with a 2 per cent solution of butyn for five minutes (anesthesia). The skin around the wound is covered with petrolatum or a zinc oxide ointment. The butyn solution is then wiped up and the wound is filled completely with a modified Carnoy solution, which is allowed to remain for five or ten minutes (usually only five minutes). This tans the tissue and acts as an effective hemostatic. Any excess solution is then removed and the wound is packed carefully, as before, with iodoform gauze. A proper dressing is applied. This process is repeated every three or four days until complete healing ensues. It is imperative to prevent bridging over by frequently and carefully testing the resultant scar for any areas of defective healing. Occasionally it may be necessary to incise the operative area two or three times to insure the formation of a solid scar. The postoperative pain was trivial. A few patients complained of some discomfort for an hour or two after the treatment, but no patient complained of disabling pain. In most cases there was no purulent discharge after the first application of the sclerosing solution. There was rapid filling in of healthy granulation tissue. The minimal time required for complete healing was about four weeks and the maximum was ten weeks. The number of treatments varied from a minimum of eight to a maximum of twenty-two. The total average number of treatments after the initial incision was 16.2. There was absolutely no hospitalization, no loss of time from work or pleasure and no recurrence. In every instance a firm, simple, freely movable incisional scar formed, completely free from residual symptoms.

 Vascular and Renal Complications of Pregnancy. W. W. Herrick, New York.—p. 429.

Viruses and Virus Diseases.—Rivers emphasizes the following points: There is no adequate reason why inanimate agents cannot induce infectious diseases. Nor is it sensible to state that protozoa, fungi, bacteria, spirochetes and rickettsiae are the only forms of living organisms capable of producing

such maladies. With regard to the nature of viruses there are three possibilities: Some of the viruses may be infinitely small living organisms, the midgets of the microbial world, possessed of a nature similar to that of living entities of sorts already known, ordinary bacteria and unicellular animals, differing from them only in respect to size; others may represent forms of life that are as yet unfamiliar, while still others may be inanimate transmissible incitants of disease. One, two or all three of the possibilities may be found to hold. Consequently, final decision regarding the matter should be deferred. In spite of the fact that some infectious agents may turn out to be fabrications of their hosts, one can safely say that no one has yet established the spontaneous origin of a single infectious disease and that regarding such diseases the law of obligate communicability still prevails.

Treatment of Bronchiectasis by Pulmonary Lobectomy.

—Lindskog performed lobectomy in ten consecutive cases of bronchiectasis. The ages of the patients ranged from 10 to 43 years. The disease was bilateral in two and unilateral in eight. The shortest duration of symptoms prior to operation in any instance was six months, the longest from fifteen to twenty years. Cough and sputum were present in all. Hemoptysis was present at some time in seven of the ten cases and was recurrent and severe in six. Clubbing of the fingers was present to a noticeable degree in seven instances and was quite marked in several of these. The operative removal of the affected lobe or lobes was carried out in one stage, if the pleural cavity was found obliterated by adhesions at the time of the primary operation. This occurred in six cases. In three a two stage operation was done, the first stage consisting simply of thoracotomy, exploration and dissection of the affected lobe and the freeing of the pulmonary ligament followed by a mechanical abrasion of the parietal pleura with gauze to promote the formation of

adhesions. The chest was then closed without drainage and the actual lobectomy was performed from two to six weeks later. At the time the diseased lobe or lobes were removed, the remaining cavity in the thorax was drained with a rubber tube or intercostal catheter until the cavity was entirely obliterated. The closure of the remaining space is effected by a compensatory enlargement of the residual lobe or lobes, elevation of the diaphragm, shift of the mediastinum and some contracture in the bony thorax. Evidences of bronchial fistulas in the healing hilus appeared postoperatively in seven instances, usually during the second week. All closed readily and spontaneously without further procedures. The postoperative hospitalization ranged from five to eleven weeks. There has been one operative death. The other nine patients are all living; the one operated on most recently is still in the hospital. Six patients are apparently in excellent condition, either cured or so greatly improved that they are able to lead a normal life. Four of these patients are completely free of cough and sputum, and two have occasional cough and sputum to a maximum of from 5 to 10 Gm. daily. Only one patient is considered to be in poor condition. In this instance a middle lobe was removed after several cautery operations had been performed by several surgeons for abscess of the lung. A lobectomy is contemplated for the remaining disease of the lower part of the right lobe. No patient has experienced a recurrence of hemoptysis. All have gained weight. None have suffered dyspnea after convalescence even with moderate exertion. A reduction in the available respiratory space has not been observed.

Clostridium Welchii in Spreading Peritonitis.—Mingle and his co-workers induced spreading peritonitis in twenty dogs which had previously been immunized against Clostridium welchii toxin, in order to ascertain what proportion of the animals so immunized would survive the infection. No other treatment was given. Spreading peritonitis was induced by opening the abdomen under strict aseptic precautions, ligating the appendix at its base, dissecting off and ligating the mesentery and administering 2 ounces (60 cc.) of castor oil. Of the twenty dogs, thirteen lived and seven died. This mortality may be compared with a control mortality, previously established in

earlier investigations, of more than 91 per cent. The marked drop in mortality in this group as compared with the control group leads one to believe that the toxemia accompanying spreading peritonitis may be largely produced by the toxin of *Clostridium welchii*.

Excretion of Alcohol in Saliva.—Friedemann and his collaborators devised a simple and reliable procedure for the collection of mixed saliva. In addition to simple diffusion, other factors probably also affect the concentration of alcohol in saliva. However, the relatively slight differences which they found in the concentration of alcohol in human blood and saliva do not prevent its application for physiologic study and for medicolegal purposes. The mouth is rinsed thoroughly several times; at least five minutes should elapse before the saliva is collected, during which time a small square of petrolatum is chewed. About 5 cc. or more, if possible, of saliva is collected in a small test tube (18 by 200 mm.) which is provided with a tightly fitting stopper. The tube should contain approximately 10 mg. of sodium fluoride to preserve the sample. For best results the sample should be kept in the refrigerator and all analyses should be made within twenty-four hours. For collection of subsequent samples it is not necessary for the subject to rinse the mouth, unless alcohol has been taken in the intervening period. For determining the alcohol content of the body, 1 cc. of saliva is transferred to a 300 cc. Kjeldahl flask. The pipet is allowed to empty slowly, since saliva is viscous. The distillation and final oxidation are then carried out by the method of Friedemann and Klaas. Samples of 1 cc. of blood and urine were similarly analyzed and compared. It was found that the concentration of alcohol in mixed saliva more closely approaches that of venous blood than does the concentration of alcohol in the urine. For this and for technical reasons the use of saliva is proposed for medicolegal purposes.

Detecting Subclinical Scurvy.—Of the single determinations for detecting and grading subclinical scurvy the blood assay, Sloan believes, is the most informative but the saturation tests yield more precise and quantitative information. The added difficulties of the latter preclude their use in routine work, while the simple blood examination is one easily adaptable to hospital routine. For thorough study of the vitamin C reserves and rate of consumption the saturation tests, and particularly the blood curve, are more satisfactory. It is probable that these procedures will supplant the capillary resistance test because of their greater dependability. The capillary resistance test is the simplest procedure and it may be tested at the bedside, but its greatest drawback in adults in the present study was the occurrence of falsely negative results due to

severe anemia. The most precise and dependable method of determining the degree of saturation of vitamin C is the determination of the rate of absorption of an injected dose from the blood stream. The rate of excretion of a test dose is less precise but quite dependable.

Superimposed Infection in Rheumatic Heart Disease.—Subacute bacterial endocarditis has generally been considered a superimposed infection when it occurs in cases of rheumatic cardiac disease. Pending the elucidation of the bacteriology of rheumatic fever, the term "superimposed" infection must be used with the reservation required by the allergic hypothesis. Subacute bacterial endocarditis is not the only superimposed infection found in rheumatic cardiac disease nor is it the most frequent. In a series of thirty cases selected as representative of rheumatic cardiac disease, Friedman and Lisa found evidence of superimposed infection in the heart in twenty-two cases. Of these, only one presented the clinical course of subacute bacterial endocarditis. The others included acute bacterial endocarditis, septicemia, erysipelas, pneumonia and peritonitis. In most of these cases, acute inflammatory, non-rheumatic lesions were found in the myocardium. In many also there was acute endocarditis which was neither bacterial nor rheumatic. Its frequent association with acute nonrheumatic myocarditis suggests that these endocarditides should be included as one of the cardiac sequelae of superimposed infection.

Poliomyelitis.—Seventy-nine cases of poliomyelitis were admitted to the University and Minneapolis General Hospitals from July 1 to Dec. 31, 1937, and of this number twenty-nine patients had some respiratory distress. Physicians tend to place all their patients with respiratory difficulty in the respirator. Stoesser and Sako feel that this is a poor pro-

cedure, as some patients are made worse while in the Drinker respirator. The most important problem is the careful selection of the patients for treatment. In cases in which there is a direct paralysis of the muscles of respiration innervated by the nerves from the dorsal and cervical spinal cord the patient cannot sleep, but when he is placed in the Drinker respirator the response is usually dramatic. The cyanosis disappears and the face assumes its natural color and expression. After the patient's breathing and the respirator become synchronous, he falls into a deep sleep which may last many hours. In bulbar disease in which there is involvement of the nuclei of the cranial nerves with apparent injury of the respiratory center, the patients usually do badly in the respirator. Nine of the authors' patients had pharyngeal paralysis with some interference in proper breathing. None were treated in the Drinker respirator and all recovered. Two patients also had facial paralysis, and this cleared up satisfactorily. There were, however, six cases of the bulbar type with definite respiratory difficulty. Two patients were placed in the Drinker respirator but they did poorly and died in a short time. It was apparent that the machine caused aspiration of material from the throat and at the same time overcame the reflex choking and coughing by which this material could be ejected. The remaining four patients were treated by elevating the bed to facilitate drainage, suction of secretion, postural drainage, fluids parenterally and transfusions. The progress in all but one was favorable. In bulbosplinal cases if the paralysis of the pharynx is bilateral, as indicated by a total inability to swallow, the machine is ineffective. This was easily demonstrated by the fact that five of six bulbosplinal patients were placed in the Drinker respirator and none survived. They all had a bilateral paralysis of the pharynx. The one patient who was not put in the Drinker respirator therapy was not gravely ill. There was only a partial involvement of the muscles of respiration and a unilateral pharyngeal paralysis. This patient recovered. In conclusion the respirator is effective in patients with spinal respiratory involvement. In the bulbar type of paralysis with glossopharyngeal and vagal involvement, the respirator often offers little help.

Pneumococcic Meningitis.—Of the ninety-nine patients with pneumococcic meningitis seen at the Boston City Hospital between November 1929 and June 1936, none recovered except six of the ten whom Finland and his co-workers treated with sulfanilamide alone or with serum. The procedure adopted was as follows: 1. Complete and frequent drainage of the spinal fluid was carried out. 2. Continuous large doses of sulfanilamide by mouth or by subcutaneous injection, if necessary, were used immediately. The optimal dose has not been determined. Sodium bicarbonate was given with each dose. 3. The pneumococcus was identified as rapidly as possible and sufficient specific antipneumococcus serum was given intravenously to establish a balance of antibody in the circulating blood. 4. To insure adequate amounts of spinal fluid for drainage, the fluid intake was moderate. 5. About two hours after a reasonable dose was given, blood was withdrawn from the patient and the serum was separated. 6. Following the removal of spinal fluid, at the time of the next lumbar puncture, this serum was given intraspinally (from 5 to 10 cc.). This procedure may be repeated after subsequent lumbar punctures, if necessary. 7. Lumbar punctures were repeated until the fluid was normal. The frequency was determined by the initial pressure of the fluid and its cellular and protein contents. 8. Transfusions were given after the first week of sulfanilamide therapy if anemia developed and were repeated, as necessary, until the drug was discontinued (after from seven to fourteen days of sterile fluids). These procedures serve to ensure a balance of antibody in the blood stream and to control the

bacteremia. They should, in most instances in which the sulfanilamide effectively reduces the infection, provide an adequate amount of antibody and complement in the optimal proportions and in a medium which is likely to give the least local or general reaction and the greatest antibacterial effect. A summary of the case histories and laboratory studies is given.

Nicotinic Acid in Anemia.—Hansen-Pruss administered nicotinic acid (Eastman) to three patients with pernicious anemia, one with hyperchromic anemia and liver disease, one with idiopathic hypochromic anemia and two with myeloid leukemia. Each of the seven patients was given 60 mg. of nicotinic acid daily, by intramuscular or by intravenous injection. In two cases an evanescent flushing and subjective feeling of warmth followed the first of several injections. No other reactions were observed. In addition to frequent peripheral blood counts, cell counts were done directly on material aspirated from the sternal bone marrow. The nicotinic acid had no antianemic value in the seven instances. The only hematologic change observed was a temporary depression of myeloid function, as indicated by a drop in the leukocyte count of the bone marrow. This fall was not mirrored in the leukocyte count or in the Schilling hemogram of the peripheral blood. Nicotinic acid apparently had no effect on the platelet count. Thrombopenia in the cases of Addison-Biermer anemia, when present, persisted until treatment with liver was instituted.

Epidemiology of Poliomyelitis.—Dauer gives information on the prevalence of poliomyelitis in the United States since 1916, reviews the epidemiology of the disease as it was presented in 1916 and its developments during the succeeding twenty years, and presents in detail the distribution of the disease by counties from 1933 to 1937 inclusive. A study of case fatality rates disclosed the fact that there were wide fluctuations from year to year in some states, suggesting that cases were well reported in epidemic years and poorly reported in the intervals between epidemics. In other states case fatality

rates fluctuated within fairly definite limits, which might be regarded as an indication of fairly uniform reporting. The decline in case fatality rates in the last ten to fifteen years might be explained on the basis of more complete reporting of cases, the inclusion of more abortive and nonparalytic cases among those reported, of a difference in the virulence of the virus, a more resistant host, or by a combination of two or more of these factors. From 1916 to 1937 inclusive, outbreaks of poliomyelitis have shown two characteristics: In 1916, 1921, 1927, 1928, 1931, 1934 and 1937 they were widespread and affected fairly large areas. In the intervals between these widespread outbreaks, localized epidemics occurred in more or less restricted regions. The same geographic area is not always affected in successive outbreaks. The most definite change in the occurrence of poliomyelitis since 1916 has been in the age distribution of persons affected. In 1916 and previous to that time, from two thirds to three fourths of the cases reported were in children less than 5 years of age, while one fifth or less were in persons 10 years of age and over. Since 1930, from one third to one half of the reported cases have been in children less than 5 years of age and from one fourth to one third in persons 10 or more years of age. This change has been a gradual one over the last twenty years. Except for this change in age distribution there seems to have been little change in the behavior of the disease in recent years. The disease is found in all parts of the country.

Intestinal Tuberculosis.—Stone and Sheekles derive their material from the total hospital patients admitted during a period of ten years (1927-1937). From the 55,867 hospital patients, 10,545 (18.9 per cent) were in the medical service. There were in this decade 739 medical cases with a diagnosis of tuberculosis in some form. Almost 40 per cent of all the hospital cases with tuberculosis during the period came to necropsy. Sixty cases showed enteric lesions of tuberculosis

at necropsy. The condition was somewhat more than twice as frequent in the Negro. The highest incidence of intestinal tuberculosis is from the third to the sixth decade inclusive or, roughly, the same as that of tuberculosis in general. The majority of the cases of intestinal tuberculosis developed in the course of chronic ulcerative pulmonary tuberculosis, and in considerably more than half of these it was a late event in an already hopeless disease. In a small percentage of cases it was present for long periods and may well have been the precipitating cause of death. The intestinal disease was always secondary; not a single case of primary tuberculous enteritis was observed. Special types of x-ray investigation of the digestive tract of patients with tuberculosis in all forms must be undertaken if the diagnosis of intestinal tuberculosis is to be made with any degree of accuracy and at a time when treatment may be expected to be beneficial.

Schistosome Dermatitis.—Edwards and Brackett state that investigations to date have revealed not only the presence of schistosome cercariae in a number of Wisconsin lakes but also their dermatitis-producing character when applied to the human skin. The commonest type of "swimmer's itch" in Wisconsin is the schistosome dermatitis of Cort. In the typical case, acquired by bathing, wading or working in infected waters, the patient does not ordinarily experience any unusual sensation until he has left the water. In from five to twenty minutes after one has left the water a tingling sensation may be felt on the portions of the body that were submerged. Within a short time, usually in from half an hour to two hours, this becomes a distinct itch and pinpoint size, red macules appear in the same area. The latter progress to papules in the course of the next twelve to twenty-four hours. After a day or so many of the papules are surmounted by a pinpoint crust, which frequently surrounds a hair follicle. The mature lesions resemble chigger bites. Some of the lesions may progress to pustules, especially if they are numerous and itching is severe. This seems to be due to secondary infection resulting from scratching. The lesions fade and disappear after a week or two but may leave a red or brown stain for some time. Cercariae which cause dermatitis are larvae of trematode worms of the family Schistosomidae. The members of this family are parasitic during their adult stage in the hepatic, portal and mesenteric veins of birds and mammals. There is a period of development in the snail. Schistosome cercariae which produce dermatitis are free swimming, colorless, multicellular organisms about 0.7 mm. in length. Snails convey the cercariae to man but birds or animals or both distribute the parasites from lake to lake. If a person is exposed to water containing them, some of them may penetrate his skin and produce the characteristic dermatitis. Man is, however, an abnormal host and the cercariae die after penetrating his skin. In Wisconsin the snails seem to become infected with the miracidium stage of the parasite sometime in the spring. Since penetration of the skin by the cercaria seems to be influenced by evaporation of the infected water which clings to the surface of the body following submersion, the disease could to some extent be prevented by immediately washing off the exposed areas with noninfected water and thorough drying. The additional use of soap or a mild antiseptic such as alcohol seems to be of further value. The simplest and most effective means of controlling the disease is to attack the snail vector of the parasite. Snails may be combated by the simple process of manually removing them from the beaches or by killing them with poisons. Copper sulfate will kill them, but it will also kill other forms of aquatic life and therefore treatment should be carried out only under the direction of the proper health or conservation authorities.

Surgical Treatment of Multiple Sclerosis.—Koch and de Savitsch report twenty-six operations (ganglionectomy and sympathectomy by the anterior approach), most of them in cases of advanced disseminated sclerosis. The operation was performed in fifteen cases of disseminated sclerosis, ten of which may be considered for statistical study, as from six to fourteen months has elapsed since the operation. Eight of the ten patients are alive today. Practically every patient, including the four most recent ones, responded favorably to this surgical procedure, which is in agreement with the observations of Wetherell. At no time were there any immediate unfavorable effects in the development of symptoms. In the majority of cases a remarkable degree of amelioration has taken place. All the patients were in an advanced stage of the disease. The authors are attempting now to operate on patients in earlier stages, in whom the evaluation of results will be considerably more difficult. Of the two fatalities one was due to embolism and the other patient died several hours after the operation from hemorrhage due to the slipping of the ligature from the thyrocervical trunk. The anticipated Horner's syndrome was observed in every patient, though enophthalmos had a tendency to regress, becoming quite inconspicuous within a few months. For about two months following the operation the patient must avoid any extreme exertion, as it may be accompanied by weakness and even collapse. After the operation some patients complain of pains in the shoulder and arm on the side of the operation. The pain lasts but a few days and usually requires no attention. In persistent cases the injection of a small amount of procaine hydrochloride gave immediate and permanent relief. Another complication seen in about one third of the cases is incontinence, which always disappeared after the first forty-eight hours. Occasionally the arm on the operated side becomes paralyzed, but the paralysis lasts only a few days and there are no residual effects.

Carcinoma of Ileocecal Valve: Report of Three Cases and Statistical Survey. H. Wapshaw.—p. 280.

Treatment of Mental Disorders with Metrazol.—Wyllie used metrazol in treating twenty patients with advanced schizophrenia, eight women and twelve men. Physical improvement was observed in seventeen. Those who were emaciated gained

weight rapidly, gaining from 14 to 21 pounds (6.4 to 9.6 Kg.) in two months. Their appetites improved and their complexions became healthier. These seventeen patients also showed mental improvement. They showed increased contact with reality. One patient who had been mute for more than ten years, and who had failed to react to sulfur in oil and to sodium amytal, was enabled to speak. The others became more accessible and spoke more freely. Urinary incontinence was corrected in four patients. Some of the patients who were previously idle were induced to occupy themselves. A patient with profound melancholia and one with depressive stupor recovered, two with chronic melancholia were very much improved, two with resistive stupor showed slight improvement and are still under treatment, and one with obsessional neurosis improved and is still under treatment. One female patient suffering from schizophrenia complicated by epilepsy was treated. Seizures were easily induced with a dose of 5 cc., and she quickly regained consciousness. Owing to the simplicity and safety of metrazol therapy it is likely to supersede insulin shock therapy.

Splenic Anemia and Banti's Syndrome.—Howells reviews the results of treatment in ninety-four cases diagnosed as splenic anemia or Banti's syndrome. Of these fifty-one were treated by splenectomy and forty-three medically, the choice of treatment being largely a matter of opinion. The medical treatment consisted of symptomatic measures for anemia, indigestion, pain, hematemesis and so on. Splenectomy does not seem to improve the expectation of life or prevent the progress of cirrhosis of the liver or of the anemia or the occurrence of hematemesis, and therefore there is no logical reason for retaining it as a routine. It may be justifiable to remove a spleen that is causing severe pain, but the operative risks must be considered. Iron appears to be of value whether the patients have undergone splenectomy or not, but the anemia is often unaffected by any form of treatment. The expectation of life in the different stages of the illness is little altered by splenectomy. The results appear to be slightly more favorable in the group of medical cases but this may be due to the operative mortality after splenectomy. Of the fifty-one patients on whom splenectomy was performed, nine died as a result of the operation, and in the other seventeen fatal cases cirrhosis of the liver was the cause of death in six cases, hematemesis in four, peritonitis in two, intercurrent disease in two, pyemia in one and anemia in one. In one case the cause was not clear. Of the twenty-one patients receiving medical treatment who died, cirrhosis of the liver was the cause of death in ten cases, hematemesis in nine and acute thrombosis of the portal and mesenteric veins in one, and in one case the cause was not discovered. The final results, based on the progress of both the hepatic disease and of the anemia in the two groups of patients, show that twenty-two of the fifty-one splenectomized patients and twenty of the forty-three medically treated patients improved.

Cyclohexyl-Ethyl-Triazol and Schizophrenia.—Mayer-Gross and Walk used a 5 per cent solution of cyclohexyl-ethyl-triazol for the induction of convulsions in the treatment of thirty-three cases of schizophrenia. Behrens, Dinkler and Woelckhaus found the compound to have advantages over the 25 per cent solution of pyridine betacarboxylic acid diethylamine

and metrazol. Convulsions were readily induced by quantities of the compound ranging from 0.7 to 2.5 cc. given intravenously. The majority of patients require between 1.2 and 1.8 cc. The type of convulsion produced is, with correct dosage, the full major epileptic fit. The excretion of triazol appears to be somewhat slower than that of metrazol; consequently the injection need not be given with any special rapidity, though the smallness of the dose makes it easy to do so. Should the amount given fail to induce a fit, a supplementary dose of from one-third to one-half the original dose is sufficient to bring on the fit if given up to two minutes after the original injection. Sclerosis of the veins has not occurred in any case. When given intramuscularly, approximately twice the intravenous dose is required, though there are individual variations and it is best to begin with a somewhat smaller dose. After the fit, recovery is usually rapid, but there may be a short period of restlessness, as with metrazol. Routine premedication with $\frac{1}{100}$ grain (0.00065 Gm.) of atropine, given one hour before the treatment, completely abolishes vomiting. Amnesia for the effect of the drug appears to be more complete than with metrazol.

Treatment of Epidemic Encephalitis by Normal Serum.—Eleven patients with epidemic encephalitis were treated by So with serum of normal persons intraspinally. Serums were obtained from four healthy members of the patients' families and three normal men in the laboratory. These serums were not inactivated nor was a disinfectant added. Serums were never used if they were older than three days. The serums were kept in the ice box. The quantity of serum used was from 3 to 8 cc., and it was introduced slowly into the spinal cavity by lumbar puncture. Before the serum was administered a narcotic was injected, as the injection of the serum occasionally caused temporary stimulating symptoms. The most remarkable thing about the treatment is the prompt lowering of the temperature of the body (from several hours to twenty-four hours) and the rapid recovery of consciousness. A larger quantity of serum appears to be more effective than a smaller dose, especially in severe cases. Even in advanced cases the administration of normal serum produces a rapid fall of temperature. There appeared to be no difference in the effectiveness of the serum, whether it was taken from blood relatives or otherwise.

Production of Artificial Argyria in Animals. J. Lenartowicz and B. Jalowy.—p. 483.
Traumatic Marginal Alopecia. H. Ribeiro.—p. 495.

Cholesterolemia in Psoriasis.—Gaté and his associates conducted investigations in order to verify the theory according to which disturbances in the lipoid metabolism are the cause of psoriasis. They first cite the different clinical factors that have been advanced in favor of this theory, such as that most patients with psoriasis are well nourished, that the incidence of psoriasis decreased in Germany during the war when the fat content of the diet was low, and that the scales of psoriasis have an abnormally high fat content. Further, they cite biochemical and therapeutic factors in favor of this theory and mention authors who studied the cholesterol content of the blood and the therapeutic efficacy of diets with a low fat content. They studied the cholesterol content of the blood in thirty-six cases of psoriasis at the time of the severest stage of the eruption and also, when possible, after the attack. In some of their patients they employed a diet with a low fat content, but a strict enforcement proved difficult and so there were only a few rare cases in which they used this dietetic treatment to the exclusion of all others. They excluded all foods with fat content of more than 30 per cent and included only limited quantities of the foods with a fat content between 3 and 12 per cent. They give a list of the foods that are prohibited and of the foods that are permitted. The diet made up of the latter foods was sufficiently varied and palatable. Contrary to the observations of other investigators, the loss of weight was slight in the authors' cases. The authors say that the cholesterol content of the blood was normal or below normal in 30 per cent of the cases, whereas in all other cases it was either above normal or at the upper limits of normality. Moreover, tests made during the time of improvement or cure revealed in the majority of cases a considerable reduction in the cholesterol content. However, there was one case in which a clinical amelioration was accompanied by a slight augmentation in the cholesterolemia. The therapeutic results of the fat deficient diet seem interesting in spite of their small number. The authors noted one failure, but in four other cases they obtained a considerable amelioration either with the diet alone or together with local treatments. They think that the dietetic treatment is indicated in association with the customary treatments, not only in order to promote their action, but especially in order to prevent recurrences.

- Leprosy in Brazil and Its Prophylaxis. H. C. De Souza-Araujo.—p. 1119.
*Treatment of Secondary Infectious Rheumatism by Azo and Nonazo Derivatives of Sulfanilamide. M. Ferond.—p. 1125.

Treatment of Rheumatism by Derivatives of Sulfanilamide.—Secondary infectious rheumatism, according to Ferond, develops in the course of an infection and involves a lesser number of articulations than does acute rheumatism. The articular swellings are usually less mobile than in Bouillaud's disease and subside less readily. Ankylosis and considerable deformities and tendinous retractions and even suppuration occur more frequently. The capsules and periarticular bursae are always involved. Sometimes they are alone involved and the articulation proper is unimpaired. In the majority of cases of secondary infectious rheumatism it is the actual presence of the infectious organism in situ which produces the articular manifestations. The treatment with salicylate has little or no effect in this form of rheumatism. Articular puncture often permits the detection of streptococci, staphylococci, pneumococci, gonococci and so on. From the immense group of secondary infectious rheumatism some forms stand out because of their frequency, because they have been studied more thoroughly or because an efficacious treatment is available for them. In this connection the author cites gonorrheal rheumatism, acute syphilitic rheumatism and the rheumatisms that develop after scarlet fever, erysipelas, puerperal infection, pneumonia, typhoid, influ-

enza and cerebrospinal meningitis. Until recent years the medicinal treatment was not effective against the majority of the micro-organisms responsible for the aforementioned forms of secondary infectious rheumatism, but the discovery and the therapeutic employment of a series of chemical derivatives that are efficacious against gonococci, staphylococci, streptococci, pneumococci, meningococci and others seem to make possible practically a specific chemotherapy of a large number of cases of secondary infectious rheumatism. The author gives the formulas of the new preparations, cites their action on different pathogenic organisms and discusses their experimental toxicity and their absorption, elimination and mode of action. In evaluating their clinical activity and their therapeutic value in acute secondary infectious rheumatism he emphasizes that these medicaments occasionally seem to give rise to complications. However, he thinks that these substances, when employed promptly in the treatment of secondary infectious rheumatism, will prove valuable in preventing late complications.

Cold Abscess of the Thyroid Gland. A. Uraz.—p. 977.

Pyretotherapy of Lipoid Nephrosis.—Clément says that several observers have noticed that, instead of becoming exacerbated by intercurrent febrile diseases, lipid nephrosis frequently is improved by them. He was able to collect thirty-nine cases in which an existing lipid nephrosis was improved after an intercurrent febrile disease. The appearance of the fever is often accompanied at first by an exacerbation of the clinical symptoms such as reduction in the urinary output and augmentation of the albuminuria, of the edemas and of the serous effusions. After that the paradoxical clinical amelioration appears: diuresis sets in; the albuminuria decreases rapidly and may disappear; the edemas and the effusions become absorbed, and the general condition improves. The diseases that have had a favorable effect on the development of lipid nephrosis vary greatly. The only factor they have in common is that they produce a high fever for a period of several days. In the material investigated by the author, measles, either alone or combined with other febrile disorders, was the most frequent. Other febrile disorders that were found to influence lipid nephrosis were various types of pneumonia, bronchitis, rhinopharyngitis, peritonitis, erysipelas, otomastoiditis sinusitis, typhoid and so on. The favorable effect exerted by such intercurrent febrile diseases on the evolution of lipid nephrosis has led to trials with pyretotherapy. The author tried this treatment first in 1936, but subsequent bibliographic investigations revealed to him that others had tried it as early as 1931 and 1933. He gives a detailed clinical history of a boy, aged 15, who had a typical lipid nephrosis and in whom pyretotherapy produced a clinical and humoral cure which so far has persisted for eighteen months. The attacks of fever were elicited at first by injections of sulfured oil and later with an antityphoid vaccine. This and other cases corroborate the ameliorations produced in lipid nephrosis by intercurrent febrile diseases. In summarizing the observations on lipid nephrosis in the course of spontaneous or provoked fever, the author says that the existence of a nephritic element in lipid nephrosis makes it necessary to be extremely reserved in the use of pyretotherapy. In several cases in which the urine contained casts and leukocytes and in which the blood showed a certain degree of azotemia, the intercurrent febrile disease did not have favorable effects on the lipid nephrosis. The existence of these symptoms may be a contraindication to pyretotherapy. Moreover, even in pure lipid nephrosis the disorders accompanying the hyperthermia must be taken into consideration. The daily injection of progressive doses may represent too much of a load for the diseased organism. On the other hand, a short thermic attack provokes only a short phase of aggravation, which is followed by an improvement. It seems best to employ the induced fever discontinuously, at intervals of six or ten days, for example. The choice of the pyretogenic agent seems to be of little importance. The use of milk, casein, sulfur preparations, bacterial

vaccines and physical therapeutic procedures have all been known to be followed by success as well as by failure. The results obtained are not exactly in proportion to the height of the fever. Nevertheless it seems necessary that the thermic attack be of considerable intensity. The action mechanism of the fever is still hypothetical. The author hopes that pyretotherapy will greatly improve the prognosis of lipid nephrosis.

Gauthier-Villars.—p. 1015.

Granulocellular Rhabdomyoma of Tongue. J. Ducuing and Bassal.—p. 1018.

Therapeutic Properties of Vitamins.—Szent-Györgyi shows that certain misconceptions exist with regard to the vitamin C requirements of the organism. Zilva, he says, in experiments on guinea-pigs, detected that from 1.5 to 2 mg. of vitamin C maintains the guinea pig in an apparently healthy state but that a quantity about ten times greater is required to saturate the organism of the animal with vitamin C. Zilva thinks that this enormous quantity of vitamin C is entirely unnecessary, since with about 2 mg. of vitamin C the guinea pigs seem to be in perfect health. To this opinion Szent-Györgyi raises the objection that guinea pigs living in cages cannot be compared with those living in their natural habitat. He admits that 20 mg. of vitamin C seems an enormous amount but shows that guinea pigs which live in their natural surroundings in the tropics ingest approximately that amount with their daily food. He is of the opinion that the quantity of vitamin C which protects the organism against scurvy is not necessarily sufficient, because scurvy is not the first sign of vitamin C deficiency but rather a premortal, late symptom. A slight vitamin C deficiency causes no definite symptoms, so that the organism appears healthy. Man living under conditions provided under civilization is subject to a partial vitamin deficiency. This partial avitaminosis and the diminution of the power of resistance, which it involves, may lead to various disorders. On the other hand, vitamin C seems to produce favorable results in febrile diseases, during which the organism's requirements for vitamin C seem to grow. In this connection the author suggests that if diseases like pneumonia and nephritis are favorably influenced or even cured by vitamin C, it appears likely that they might have been prevented if the patient had absorbed the required amount of vitamin C.

Histologic Lesions of Gonococcic Arthritis.—Mondor and Gauthier-Villars, after reviewing the results which they obtained in biopsies in cases of gonococcic arthritis in the years 1926 and 1928, cite observations by other investigators. Since 1928 their biopsy material has greatly increased, so that now it includes forty-eight synovial biopsies (articular and tendinous), fifteen osseous biopsies on the articular surfaces and twenty-one calcaneal sections. Before evaluating the observations on this material, the authors raise the question whether the observed reactions are elicited only by the organism in question or whether they are determined also by the tissues in which they evolve. Since in the cases of arthritis treated by arthrotoomy biopsy is still not widely practiced, the authors lack sufficient material for comparison with other forms of arthritis. Moreover, in the same patient it is possible to evaluate the impairment of the synovial membrane, of the bone, of the periosteum, of the cartilage and of the periarticular tissues only relative to the resected pieces, which do not often represent stabilized forms. Finally, the age of the lesions must be taken into consideration. In evaluating their histologic observations, the authors first discuss twenty-two synovial biopsies which they made within the first two months of the existence of the disease. In eighteen of these twenty-two cases they were able to detect gonococci in the sections, whereas this was possible in only one of the twenty-six cases in which the process was older. In attempting to draw general conclusions from their histologic observations, the authors say that they were unable to find lesions that were

frankly specific for gonococcal arthritis. They think that it is impossible to base a definite etiologic diagnosis on the inspection of histologic sections, but the absence of necrosis, the precocity of the organization of the lesions and the richness of the inflammatory exudates in plasmocytes appear to them as suggestive of a gonococcal process. However, they believe that on the basis of twelve years of observation they are justified in affirming that the synovial membrane is the point of predilection of the lesions of acute arthritis; it shelters the gonococcus even in the cases in which the periarticular phenomenon seems to be the most active. Gonococci are detectable in eight out of ten cases if the examination is made during the first eight weeks. The bone is always more or less involved in the course of acute arthritis, and the term acute osteo-arthritis, which has been suggested by the authors, corresponds to an anatomic reality. Pathologic dislocations are frequent; there are osseous as well as capsular lesions which cause them. The anatomic changes that are the basis of the gonorrheal talalgias consist in a diffuse calcaneal osteoperiostitis, which far exceeds the roentgenologically visible exostosis.

*Influence of Hypnosis on Pulse: Apparatus for Automatic Uninterrupted Registration of Blood Pressure. B. Stokvis.—p. 764.

Silent Early Period of Syphilis. K. Wolpert.—p. 767.

Influence of Hypnosis on Pulse.—Stokvis says that in considering the influence of hypnosis on the pulse action it is necessary to differentiate between the influence of the hypnosis as such and that which is exerted by the nature of the hypnotic suggestions. In order to determine the influence of hypnosis on the pulse, he subjected ten healthy persons and ten persons with essential hypertension repeatedly to hypnosis. The figures given in the tables reporting the results are the mean averages of repeated tests. The feeling of the pulse, which is a disturbing factor in hypnosis, was unnecessary, because the tensograph was used. This is an apparatus for the continuous automatic registration of the systolic and diastolic blood pressure which indicates every pulse beat by a ticking sound. Discussing the influence of hypnosis as such, the author says that in healthy persons the pulse frequency decreases under the influence of hypnosis as such. The same statement applies *mutatis mutandis* to persons with hypertension. In normal persons the suggestion of rest under hypnosis usually causes a greater decrease in the pulse frequency than does hypnosis as such. The change in the pulse frequency is greatest if fear is suggested and least if joy is suggested. The suggestions during hypnosis of anger, pain and work have approximately the same effect on the pulse frequency. In patients with hypertension it is the same as in normal persons. The fact that during the hypnotic state as such the pulse frequency usually decreases is in accordance with the fact that the systolic pressure, which is dependent on the cardiac activity, decreases more during hypnosis than does the diastolic pressure, which is influenced chiefly by the tone of the vascular wall. If cardiac palpitation is suggested during the hypnotic state, neither the blood pressure nor the pulse frequency is changed. Thus it is impossible to increase the pulse frequency by the direct suggestion of an abnormal cardiac activity; to accomplish this, an emotional stimulus is required which influences the nervous system of the vessels.

*Electrocardiographic and Morphologic Researches for Right or Left Localization of Ventricular Myocardial Lesions. F. Kienle.—p. 543.

Localization of Myocardial Lesions.—Kienle states that lowering of the ST segment of the electrocardiogram taken at the extremities at the first or second derivation indicates predominant lesions of the left ventricle, whereas the same phe-

nomenon in the electrocardiograms taken in the second and third derivations shows predominant lesions of the right ventricle. His statement is supported by the results of macroscopic and microscopic studies of the heart of several patients who showed these electrocardiographic alterations for some months before death. Necropsy confirmed the diagnosis as to the presence of myocardial lesions at either the right or the left ventricle in all cases. In a case of subacute pulmonary embolism there was a lowering of the ST segment of the electrocardiogram in the third derivation. The curve was similar to that of infarct of the posterior wall. A large number of foci of necrosis of the right ventricle could be seen on microscopic study of the heart.

*Spinal Anesthesia in Cesarean Section. A. Duca.—p. 364.

Morphologic Modifications of Blood After Epinephrine Injection in Pregnancy and Puerperium. T. M. Caffaratto.—p. 378.

Spinal Anesthesia in Cesarean Section.—Duca points out the advantages of lumbar anesthesia in making a cesarean section. Cesarean section was indicated in seventy-five of eighty-six cases because of abnormalities of the pelvis. The remaining cases were of early rupture of the membranes, detachment of placenta normally inserted, central placenta praevia and eclampsia. Forty-nine patients were primiparas. The author administered 3 cc. of a 5 per cent solution of procaine hydrochloride with some epinephrine. The amount of spinal fluid removed was about 4 or 5 cc., and more than that but less than 10 cc. was removed in cases of increased pressure of the fluid. Lumbar anesthesia offers no danger or after-effects. The contraindications are large hemorrhages, acute shock, decompensated heart diseases, acute toxemia, hypotension in intestinal obstruction and septicemia with positive blood cultures. Lumbar anesthesia has various advantages, especially the speed of inducing it in about ten minutes without any previous preparation of the patient, the complete insensibility of the lower half of the body, relaxation of the abdominal muscles, lack of nausea and other abdominal disorders, and especially the hemostatic conditions of the operative field. The author reviews the theories of the enervation of the uterus and states that spinal anesthesia induces an energetic contraction of the uterus with consequent hemostasis during cesarean section.

Functional Factors in Roentgen Aspects of Normal Lung. A. Salotti.—p. 541.

Roentgen and Radium Therapy of Laryngeal Papilloma. E. Rosti.—p. 547.

Spontaneous Fractures of Ribs in Pulmonary Tuberculosis.—After examining the roentgenograms of the thorax in a group of 4,570 adult patients of both sexes who were suffering from pulmonary tuberculosis, Sabbione found spontaneous fractures of the ribs in nineteen. There was no history of trauma. The fracture was caused by coughing or sneezing. According to the author, spontaneous fractures of the ribs in the course of pulmonary tuberculosis are rare. They take place in adults over 40 or 50 years of age who are suffering from grave forms of pulmonary tuberculosis. The condition is more frequent in women than in men and takes place in either side. It is caused by osteoporotic atrophy which develops in the course of pulmonary tuberculosis from insufficient fixation of calcium by the bones. The diagnosis is made from the type of pain which is constant and intensified by coughing, sneezing and pressing of the rib during palpation. The fracture shows in the roentgenograms from fifteen to twenty days after it takes place, with the typical aspect of callus. Spontaneous fractures of the rib evolve as fractures of any other type, with complete healing

in two or three months. They seem to have a prognostic significance. In all the cases seen by the author the general and pulmonary conditions rapidly grew worse after the occurrence of the fracture.

*Posttraumatic Parkinsonism. S. Chichilnisky.—p. 1420.

Factors of Success or Failure of Peridural Anesthesia. E. S. Sammartino.—p. 1429.

Posttraumatic Parkinsonism.—Chichilnisky discusses the etiologic role of cranial trauma in parkinsonism and reviews the literature on the subject. According to the author the existence of posttraumatic parkinsonism is proved. The diagnosis is made after verification of the following conditions: absence of any history of the patient having had encephalitis, presence of violent cranial trauma and, generally, of a period of incubation of the disease, progressive uninterrupted evolution of the disease without appearance of mental symptoms and a constitutional predisposition. Loss of consciousness is not necessary in cerebral concussion which may be demonstrated by other symptoms of shock. The period of incubation between trauma and first appearance of the symptoms generally varies from eight to ten months. In rare cases it may be either longer or nonexistent. The disease develops without any remission. The syndrome is caused by hemorrhagic lesions either at the optostriate nuclei or at the cortex of the frontal lobe. There is an evident correlation between posttraumatic parkinsonism and Pierre Marie's syndrome. The two syndromes generally coexist. From a medicolegal point of view the patients have a permanent total incapacity. Two cases are reported.

*Recurrence of Gallstones. G. Zopff.—p. 389.

Results with Resection in Gastric Duodenal Ulcers. E. Kirnmann.—p. 397.

Recurrence of Gallstones.—According to Zopff, in the last three years 202 cholecystectomies were performed at the Heidelberg clinic. During the same period forty-five (18.5 per cent) patients were readmitted to the clinic because of recurrence of symptoms. The original operation was performed from six months to twelve years before. Only eleven had their original operation at the Heidelberg clinic. On reoperation a stone was found to be present in the extrahepatic bile passages in twenty-three (51 per cent), or 9.3 per cent of the total number of patients operated on during the same period. Inflammatory alterations were responsible for the symptoms in eleven (24.5 per cent). Eight patients presented mechanical disturbances either in the biliary tract or in the intestine. Dyskinesia was assumed to be the cause in three (6.7 per cent). Enlargement of the periportal lymph nodes was found to be the cause in two cases. Carcinoma at the hilus of the liver was observed in one. There were three types of inflammatory alterations: those of the bile passages, late abscesses, and inflammation of the head of the pancreas. The patients in whom the symptoms were due to inflammation of the bile passages responded well to conservative treatment, which consisted of the passage of the duodenal sound and flushing with 40 per cent magnesium sulfate. There were four instances of late abscesses which had developed in cases of neglected cholangitis. More than 50 per cent of recurrences were due to a stone. The author believes that most of the recurring stones are these overlooked at the time of the original operation, although he does not reject the possibility of formation of new stones in the extrahepatic bile passages. In proof of the latter contention, the author cites three cases in which stones were removed from the common bile duct and in which there was congenital absence of the gallbladder. The author likewise had seen two consecutive recurrences of stones in the common bile duct. He stresses Enderlen's advocacy of an early operation for gallstones. The stones may lie a long

time in the common duct without producing symptoms, though they prepare the ground for a recurrence after a cholecystectomy. Among 202 cholecystectomies, stones were removed from the bile passages in twenty-eight cases (13.9 per cent). Because of a definite increase in mortality when the choledochus is opened, roentgenologic investigation of the patency of the duct during the operation, as proposed by Mirrizzi, was adopted in the Heidelberg clinic. In addition, they have attempted to locate the stone by transillumination of the duct. The favorite seat of a recurring stone is the physiologic enlargement of the duct just above the sphincter of Oddi, giving rise to symptoms of a valve stone with or without involvement of the pancreas. The diagnosis of the presence of a stone in the common duct constitutes an indication for operation. Choledochotomy and the removal of the stone were considered sufficient in the presence of a patent duct. Drainage was practiced only in the presence of severe inflammation, icterus and white bile. The author considers systematic medical after-treatment an important prophylactic measure in preventing recurrence of symptoms.

Carcinomatous Lymphangitis of Lungs. H. Hippe and K. Hähle.—p. 917.

Vitamin B₁ Content of Blood and Urine.—Of the three available methods for the quantitative determination of the vitamin B₁ content, Schneider and Burger used the thiochrome method of Jansen and the method of Prebluda and McCollum. They made tests on healthy persons, on patients with hyperthyroidism and on patients with cancer cachexia. They found that the daily elimination of vitamin B₁ in the urine of healthy persons fluctuates between 80 and 100 micrograms. The average vitamin B₁ content of the serum amounts to about 6.4 micrograms per hundred cubic centimeters. The percental urine value is slightly higher than the serum value and amounts to from 7 to 8 micrograms per hundred cubic centimeters. During hyperthyroidism the normal averages of the vitamin B₁ content may be doubled; that is, the vitamin B₁ elimination as well as the vitamin B₁ requirements run almost parallel to the increase in the metabolic rate, but it cannot be said that vitamin B₁ exerts an antagonistic action against the thyroid function. In patients with cancer, the increasing cachexia is accompanied by a decrease in the vitamin B₁ content as well as by an A and C hypovitaminosis. As the cachexia reaches severe degrees, the vitamin B₁ may completely disappear from the serum as well as from the urine. In this respect the behavior of vitamin B₁ is similar to that of vitamin C.

Bacteriologic Diagnosis of Diphtheria.—Helmreich points out that the Löffler serum as well as the indicator-tellurium plate of Clauberg, the two methods most widely used for the bacteriologic diagnosis of diphtheria, have the disadvantage that at least from eight to twelve hours and frequently more time is required for the diagnosis of diphtheria. It was the author's aim to develop a culture medium that would make possible a more rapid diagnosis. He cites the guiding principles that he followed in his search for the new medium and says that after hundreds of trials he found a fluid of the following composition the most suitable culture medium: 3 cc. of beef serum, 1 cc. of a 1 per cent bouillon of dextrose and 2 cc. of a 1 per cent solution of sodium acetate. The sterile cotton tampons are immersed for a short time in this mixture and are immediately put back into the test tube. The adhering serum is coagulated by heating for a period of thirty minutes in a water bath of 80 or 90 C. Testing the reliability of this method in seventy-nine cases, the author found that in sixty-

four the diagnosis could be definitely established after from two to three hours; in six others the diagnosis was established after from three to five hours, in five after from five to eight hours and in the remaining four after from eight to twelve hours. Comparative tests with the Clauberg and Löffler methods revealed that neither of these methods established the diagnosis before at least five to eight hours had elapsed, and in the majority of cases these methods required from eight to sixteen hours. He says that the fluid mixture can be stored on ice for six weeks and that the prepared swabs may be kept for about two weeks, provided they are properly sealed. The described method of rapid bacteriologic diagnosis is especially suitable for public health centers. In new cases of suspected diphtheria this method should be used together with the Clauberg and Löffler methods.

"Athermic" Effects of Short Waves. E. Hasché.—p. 1033.

Evaluation of Efficacy of Immunization Against Diphtheria. K. Hofmeier.—p. 1035.

Dangers of Intravenous Cholecystography.—Lutz and Seyfried report the clinical history of a patient who died following the injection of the contrast medium for intravenous cholecystography. The necropsy corroborated the assumption that the sudden death was caused by an acute failure of the coronary circulation. Sclerotic changes were detected on the coronary vessels, but an acute thrombosis or an infarct did not exist. The contrast medium cannot be said to have been at fault, because ampules from the same package had been used about the same time without ill effects. Although there is no definite proof that the intravenous administration of the contrast medium caused the fatal outcome (sudden heart failure may occur in coronary sclerosis without external influences), it is nevertheless probable that the concurrence had a causal basis and that the diagnostic intervention was the eliciting factor. On the basis of this observation, the authors conclude that intravenous cholecystography is contraindicated not only in hypertension and in hypotension but also in all cases in which there is the slightest suspicion of coronary insufficiency or in which a coronary spasm threatens.

Thallium Poisoning.—Brumm says that, whereas reports about industrial and medicinal poisoning with thallium preparations have become rare, there is a noticeable increase of reports on poisonings resulting from the use of thallium preparations with homicidal or suicidal intentions. The preparation that is most frequently responsible in the latter type of cases is a paste which is marketed as a rat poison and which contains 2 per cent of thallium sulfate. The author describes his observations in a case of acute thallium poisoning. The patient, a man aged 24, attempted suicide by taking two tubes of the aforementioned rat poison, or approximately 1.4 Gm. of thallium sulfate. The case is noteworthy because the patient ingested almost the maximal dose of thallium sulfate and because he developed practically all the symptoms that are characteristic for thallium poisoning: nephritis, fornication in the hands and feet, pains in the legs, acute abdominal pains, headaches, loss of appetite, insomnia, severe thirst, loss of hair, mental depression alternating with euphoria, hyperkeratoses on the hands and feet, white transverse streaks on the nails and so on. In the tenth week after the poisoning the physical condition had greatly improved, but when the patient again gave indications of suicidal intentions he was transferred for observation to the clinic for nervous disorders. Later he could be discharged as cured. Following a review of the literature on thallium poisoning, the author says that during the early stage the differential diagnosis must consider tabes or polyneuritis caused by arsenic, lead, mercury or alcohol. The diagnosis can be definitely

decided by the demonstration of thallium in the urine or stool. Since the elimination of thallium is slow, this is possible even after weeks have elapsed since the poisoning. Discussing the treatment, the author says that injections of sodium thiosulfate have been recommended and that vitamin B₁ has been known to exert a favorable influence on the neuritic symptoms. In the reported case, both of these treatments were used. At first, three ampules of a vitamin B₁ preparation were given daily by intravenous injection. Later, smaller doses of it were given at longer intervals and by intramuscular injection. The intravenous injections of sodium thiosulfate (1 Gm. in 10 cc. of distilled water) were at first given daily, later twice weekly.

*Heredity of Human Blood Group Factors. V. Friedenreich.—p. 293.
Vitamin C Balance in Patients with Hematemesis and Melena. S. Lazarus.—p. 309.

Heredity of Human Blood Group Factors.—Friedenreich states that systematic quantitative studies of the absorption ability in a larger number of A persons showed two sharply defined groups, one with marked binding ability and one with weaker ability, which are identical with Landsteiner's A₁ and A₂. With Thomsen and Worsaae he showed that of the A₁ and A₂ characteristics each depends on its gene; A₂, like A₁ and B, dominates over O but is dominated by A₁. A₂ persons cannot have A₁ offspring except with an A₁ partner, while certain A₁ persons (genotypes A₁, A₂) may have A₂ offspring without an A₁ partner but cannot in such case have O children. Recently he has seen another, rare, A variety mainly characterized by reaction far weaker than that of A₂; in some of the persons with this reaction the A characteristics could not be established by means of the ordinary factory serums. He has examined the families in seven cases, about 300 persons in all. The inheritance of this characteristic, designated as A₃, is explained by the assumption of one more allelomorph gene, which dominates over O but is recessive toward both A₁ and A₂. The complete system will thus comprise fifteen genotypes and eight phenotypes. An apparently parallel principle, the author asserts, occurs in the MN system. He cites Crome's case of deviation from the system and reports a personal case of M mother and N child. Repeated examination of the mother with selected serums, however, established a weak N reaction. She is consequently not a homozygot M but has an extraordinarily weak N factor, far beyond the hitherto known variation breadth of the N factor, and examination of the child's grandmother revealed a special hereditary variety. The genetic basis must be a special allelomorph gene called N₃, analogous to A₃ in the ABO system and dominated by the usual N gene (called N₁). Repeated examination of the partner in the case cited has disclosed the N₃ factor in the mother. The frequency of the characteristic is not yet known. These uncommon factors have a practical significance in that they may escape establishment and so lead to erroneous type determination. He considers it reasonable to assume that these subtypes are the expression of a number of mutations in a relatively unstable gene, like the well known phenomena from the animal and plant kingdoms.

*Myelomatosis: Four Cases. H. E. Nielsen.—p. 549.
Perforation of Lung in Patients with Pulmonary Tuberculosis: Character or Exudate; Diagnosis by Analysis of Pneumothorax Air. H. Harpøth and U. Gad.—p. 561.

Myelomatosis.—Nielsen says that in four cases of myelomatosis, all diagnosed within nine months, the clinical picture was dominated by pains localized in the affected bones. Roentgen and laboratory examinations contributed to the diagnosis and sternal puncture revealed the characteristic plasma cells of myelomatosis. In the two cases of hyperproteinemia and hyperglobulinemia and hypoglobulinemia there was abundant Bence Jones protein in the urine. In one case treatment with high voltage roentgen rays resulted in some improvement; in the other cases the treatment was without effect. In the terminal stage in all cases there was a moderate hypercalcemia, while the serum phosphate was normal. In two cases death occurred four and twelve months respectively after onset of the symptoms.

THE UNDERGRADUATE TEACHING OF OBSTETRICS

CHAIRMAN'S ADDRESS

E. D. PLASS, M.D.

IOWA CITY

During the past decade especially, public attention has been drawn to the high maternal mortality in this country, and many alleged contributory factors have been advanced. In certain quarters there has been a tendency to place a great part of the blame for the admittedly undesirable situation on those who are undertaking the undergraduate teaching of obstetrics. Much of this criticism has come from persons who are not now and never have been engaged in this type of instruction and who therefore do not appreciate the difficulty, in fact the practical impossibility, of providing truly adequate obstetric instruction in any medical school. It is my purpose to discuss several factors related to this problem and to offer a considered defense of the men now actually engaged in obstetric teaching.

Both the profession and the public have been reluctant to admit obstetrics to a position of parity with the other clinical disciplines, an attitude which is undoubtedly engendered by the inevitable fact that child-bearing is physiologic in the vast majority of cases and that skilled attendants are therefore rarely a medical necessity. The falsity of this argument should be obvious, since modern obstetrics is actually a field of preventive medicine, with the emphasis on avoidance of the serious complications of pregnancy and parturition—infection, hemorrhage and the toxemias—which are responsible for two thirds of all maternal deaths. This failure to adopt the principles of disease prevention is not limited to obstetrics, but there is no other field in which curative procedures should be less important.

Instruction in any clinical discipline involves didactic teaching to develop a concept of the physiologic aspects of a phenomenon or of the clinical picture of a disease, and practical contact with patients to emphasize the points previously stressed. It now seems apparent that a well rounded course in any medical subject must include both methods of approach, although there is still no general agreement as to the amount of each that may be desirable. Until early in this century purely didactic instruction alone was available, and many present-day practitioners had no actual contact with human distress and disease until after their graduation. It is of historical interest to note that in its early days this Association actually went on record as opposing

other than purely didactic instruction in obstetrics and that a former chairman of this section, in reminiscing on his early difficulties, narrated vividly his experience with a group of Philadelphia matrons who threatened to burn his maternity hospital because he was teaching his students the actual technic of delivery. That attitude has fortunately disappeared, and its disappearance has opened the way for the many educational experiments now in progress.

Generally speaking, it may be said that the didactic teaching of obstetrics in the medical schools of the country is as adequate as that of any other major clinical subject. Textbooks are well written and authoritative, and the instructional staffs are progressive, interested and alert. This point of view has been developed in the course of an eight year experience as examiner in obstetrics on the National Board of Medical Examiners. Assuming that the questions given in the clinical subjects are equally difficult and that the grading is equally strict, the percentages of nonpassing grades should be significant. Among about 2,300 candidates examined during the past five years, 8.6 per cent were failed in obstetrics, as against 7.4 per cent and 13.6 per cent in surgery and medicine, respectively. The recital of these figures does not imply that the teaching of surgery is superior or that of medicine inferior but merely stresses that obstetrics maintains a median position and is presumably as well taught as other clinical subjects. The failures were not evenly distributed among the graduates of the various medical schools represented, but no one institution was especially notable for its high percentages of successes or failures.

Stephen Rushmore,¹ secretary of the Massachusetts Board of Registration in Medicine, commented at some length on the written answers to the question "Give in detail your treatment of a patient in whom there appeared no sign of separation of the placenta twenty minutes after the birth of the child." Without indicating what type of answer might be acceptable, he recorded that 182 of 250 candidates failed. The situation described is one "with which any physician practicing obstetrics is likely to be very frequently confronted," but there is considerable doubt as to whether any group of trained obstetricians would agree on the treatment "in detail." Nevertheless, the commentator remarked "However excellent the teaching of obstetrics may be, in some respects, on this elementary problem, it has not been effective for this group of candidates" and then concluded "Perhaps more effective teaching of the fundamentals of practice is one of the lines along which progress will result in the saving of more maternal lives." It should be noted that in 1937 Massachusetts had a considerably higher percentage of failures

Read before the Section on Obstetrics and Gynecology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

¹ Rushmore, Stephen: A Note on the Teaching of Obstetrics, *New England J. Med.* 217:731 (Nov. 4) 1937.

at the state board examinations (42.1 per cent) than any other state and that 300 among the 520 candidates applying for registration were from unapproved schools.

The problem of practical training, which is also implicated in the question cited, is naturally the more difficult, and from the statistical approach it seems almost insoluble. Pregnancy and parturition are essentially physiologic in character, with the major life-threatening complications of such infrequent occurrence that only the larger hospital centers can have anything approaching an adequate experience. Even if all hospital deliveries in the country could be used for student teaching to the exclusion of any other group, each graduate would be only poorly prepared for handling other than the simpler clinical problems. In 1937 there were 932,912 births in all the hospitals in the United States, a clinical material which would have provided slightly less than 175 cases for each of the 5,377 graduates. This exclusive experience would have made these young physicians capable of conducting a normal labor safely but still unequal to handling the more infrequent and serious obstetric complications. The average student would have performed from twenty to fifty forceps deliveries, seven breech extractions, two podalic versions and three cesarean sections, certainly not sufficient to make him a capable operator. On the other hand, only one student in two would have managed a single case of placenta praevia or eclampsia, one in three a really difficult vaginal delivery, one in four a serious case of puerperal infection and one in every ten or twenty a ruptured uterus or a hydatidiform mole. Under such an arrangement, it is apparent that no one could be well trained. As a corollary, it is obvious that there is not sufficient clinical material to make each graduate a competent obstetric specialist. The Council on Medical Education and Hospitals has set a minimum of fifteen obstetric cases for each senior student as the goal of those schools which would maintain their approved status, and few graduates have more actual obstetric experience than this before graduation.

The teachers of obstetrics realize the futility of attempting to make obstetric specialists out of undergraduates, and yet their critics are, at least by implication, insisting that this should be an objective of the instructional staffs. No other medical subject is taught with so much attention to preparing the student for actual practice as is obstetrics, and yet the others are not subjected to so much adverse criticism. The surgical staff is not expected to provide practical experience in the performance of major operations or in the care of fractures and other serious traumatic lesions; in ophthalmology the student is frequently not even taught the principles of refraction; in otolaryngology he does not even remove tonsils, and in urology his experience is limited to catheterizations of the bladder and prostatic massage. Yet by inference these subjects are well taught, while obstetric teaching is condemned. Is it reasonable to expect that the medical schools can graduate men and women thoroughly trained in obstetrics but mere tyros in the other fields of practice?

The family physician has been the family accoucheur and this relationship has been carefully guarded, since it helps to keep the family under his medical wing and to preserve the desirable patient-physician relationship. Moreover, child-bearing is by tradition a function for the home and remains practically the only form of surgical experience now attempted outside hospital surroundings. The majority of the general practitioners

now assuming the obstetric care of the nation had only a meager didactic training and no clinical experience before entering practice, and yet the lay public accepted them and relied on them. The fact that they have done as well as they have is a real tribute to their intelligence and to their ability to learn through the hard knocks of inescapable necessity. Nevertheless, there must be some doubt as to whether the real emergencies are being handled in accordance with the best obstetric thought and practice. It is rare to find an older physician who has not delivered from one to three thousand women without "losing a single mother" and who is not skeptical about the validity of the maternal mortality statistics reported by the Bureau of Census. The old argument as to whether home delivery is actually safer than delivery in a hospital cannot be settled, for lack of adequate data, but there can be no doubt that the relatively infrequent obstetric emergencies cannot be handled satisfactorily and safely in the home.

The struggle to reduce maternal death rates, when viewed in terms of general practice, involves experiences so isolated that their significance may well be lost. Assuming that the practitioner has fifty obstetric cases annually, the chance is that he will observe only one truly serious complication each year and that he will not have more than one maternal death every four or five years. Such isolated experiences are not impressive and are soon forgotten. Moreover, their rarity prevents the physician from acquiring that knowledge of diagnosis and treatment which is so essential if these occasional patients are to be saved. Under prevailing conditions, the wonder is not that so many women die as a result of child-bearing but that so many are carried safely through the perils of procreation.

The general practitioner has in the past done well and is to be complimented, but there is some doubt as to whether the objectives of the present movement to save the lives of mothers can be entrusted entirely to his care. If one assumes the correctness of this discussion and admits the practical inability to provide adequate obstetric training for physicians who will enter general practice, it would seem doubtful that much further progress can be expected under the present system. The ray of hope in the situation would seem to emanate from the fact that increasingly large numbers of young men with excellent preliminary medical education are being trained in the larger teaching centers and are scattering widely over the country. Persons interested in these problems would be the last to suggest that all obstetric work be placed in the hands of the obstetric specialists, although many feel that some system should be developed which would make expert advice available for every pregnant and parturient woman in the country on the suggestion of the attending physician.

There are two real obstacles to such a program, and while neither would seem unsurmountable the solutions to be suggested involve considerable changes in medical thought. In the first place, consultation with the obstetric specialist invades to some extent the traditional patient-physician relationship, which still implies professional omniscience, and entails the risk that the patient may be so impressed by the consultant's personality or knowledge that she will seek him directly when she becomes pregnant again and the referring physician will lose a patient. If and when the practitioner comes to think first of the good of his patient and only secondarily of his local professional prestige, this difficulty will disappear and obstetric patients will

receive the best advice which the community affords, certainly the goal toward which the profession is striving and the desirability of which the public appreciates and understands. The second problem, involving the cost of such consultations for all difficult obstetric cases irrespective of financial status, presents entirely different angles. The obstetric consultant can hardly be expected to give his time and to expend his energies entirely without remuneration, and yet many patients cannot afford to pay even a modest fee. One suggestion which has been offered by certain groups implies that situations of this character may be the concern of some governmental agency and that nominal payments to both the referring physician and the consultant would be in order. It remains to be seen whether this is the proper solution, but there can be no doubt that some attention should be given to providing an answer, so that adequate obstetric care may be available to all women endangered by the more serious complications of child-bearing.

An attempt has been made to develop the thesis that didactic undergraduate obstetric teaching is on a par with instruction in the other medical clinical branches but that there is not the slightest chance for the clinical instruction of undergraduates to make them competent to handle those infrequent obstetric emergencies which contribute so materially to the scattered maternal deaths and maintain the national mortality rate incident to child-bearing. The more effective utilization of the trained and experienced obstetric specialists would seem logical but inevitably involves certain changes in medical thought which time alone can effect.

University Hospitals.

HEALTH OF THE MIGRANT

WALTER M. DICKIE, M.D.

Director, California State Department of Public Health
SACRAMENTO, CALIF.

During the past few years there has been a mass interstate migration of individuals seeking manual labor, the most extensive and persistent migration of the white population that has occurred within the United States in modern times. Beginning in 1929, immediately following the economic crash that precipitated the era of depression, this flow of underprivileged migratory laborers from the Middle West to California has continued without interruption. It flared explosively following the drought years of 1933 to 1935 and assumed truly enormous proportions during the years 1936 and 1937. By no means has it stopped. Every month brings thousands of these migrants, most of whom travel by automobile, across the border lines of California.

In the last six months of 1935 no less than 57,017 migratory laborers entered the state, 90 per cent of whom were white. In 1936 they came in even greater numbers, and in 1937, according to the official records of the United States Farm Placement Service, 104,796 individuals seeking manual employment arrived at border checking stations, by automobile. Of these, more than 78,000 were from the nineteen drought states of the central and southern Middle West. In that year 59,077, or 57.4 per cent of the total number, came from six states, Oklahoma, Texas, Missouri, Kansas, Arkan-

sas and Arizona. From Oklahoma alone came 21,709 of these people and from Texas there came no less than 8,723. It is probable that many more entered by other means of transportation.

A total of 259,665 refugees was checked at border stations during the two and one-half years beginning at midyear of 1935, through 1936 and 1937, most of whom came from the drought states. The number coming from nineteen drought states in 1937 is shown in the accompanying table.

There are many causative factors in this mass movement of migrants from the Middle West, chief of which are:

1. Drought.
2. Floods.
3. Supplanting of manual labor by farm machinery.
4. Crop failures.
5. Low market prices of cotton.
6. Planting restrictions imposed by the federal government.

Since a large portion of these people were share croppers who cultivated small pieces of land and divided proceeds with land owners, they were not tied down to land ownership and, on the sudden appearance of an economic calamity, were free to make immediate departure from an unfavorable environment to search for a new source of income.

The common type of migrant that has entered California during the past two years is of native white stock, a young adult, married, with a family of several children who accompany him on his travels, all undernourished, of limited or no education, lean, brown, hardy and physically able to endure considerable hardship. In his native environment his diet, as well as that of his forebears, consisted chiefly of pork, cornmeal and potatoes with few green vegetables or fruits—little or no variety. For generations people on the isolated plains of this country have existed on such meager fare.

At the same time that unfavorable economic conditions arose in the Middle Western states, greatly increased acreages for the growing of cotton, vegetables and other products were developed in California. In fact, it is estimated that 30 per cent of the large cotton plantations of the United States are now located in California and that 60 per cent of the large-scale fruit and truck-garden ranches are in this state.

There is a definite need for seasonal agricultural labor in California, and the United States Department of Agriculture estimates that 200,000 laborers are needed to harvest the state's crops at the season's peak. The arrival of great numbers of migratory laborers does not coincide with the harvest period, however, and in spite of the fact that their services are needed urgently when crops have matured, between seasons they often constitute economic burdens on local communities. The supply and demand are not regulated for the benefit of either the growers or the harvest hands. This fact has resulted in unprecedented confusion and in physical suffering due to inadequate housing, floods and other conditions leading to physical discomfort and illness. The local communities and the state and federal agencies were totally unprepared for this explosive and unannounced invasion, but machinery was developed for providing relief, housing, food, medical and nursing care, services in child and maternal welfare, immunization against communicable diseases and other standard public health procedures.

To absorb into a commonwealth nearly 260,000 indigents within a space of thirty months, provide them

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

with manual labor in season and out, feed those without funds, provide housing, medical care, nursing and general public health services would tax the resources and ingenuity of any government. Acting together, local, state and federal authorities have surmounted legal, financial and other obstacles and today, regardless of citizenship, legal residence, race or color, adequate provision is made for safeguarding the health of migrants and for providing health protection for local residents. Work is provided whenever and wherever possible, medical care and hospitalization are given, with doctors of medicine and hospitals receiving compensation for services rendered. Not all of these benefits came at once, but with the development of a definite plan a standard and workable program of action has become a reality.

With the influx of these hordes of people who establish camps along the back roads, on ditch banks and in deserted barnyards, living in tents, packing cases, shacks and tin can shelters it became apparent that a problem in public health and welfare had arrived. The

California State Department of Public Health recognized this fact and local health officers became particularly aware of it, as did also growers of cotton, fruits and vegetables. A sincere attempt to provide suitable housing for these refugees was made by large numbers of landowners but their efforts were applicable to relatively few, because of the magnitude of the migration.

The California State Department of Public Health, in cooperation with the United States Public Health Service, for two years has carried on active field work in those rural areas of the state where migrants have located. Of first importance, it has been determined, is the provision of adequate food for these migratory families. By heritage they have become accustomed to a diet lacking both in quantity and in essential food elements. As a result, they brought with them in their migration the heritage of years of malnutrition and dietary habits which are not easily adaptable to the great variety of fruits and vegetables found in California. In a recent survey made by the Bureau of Child Hygiene, State Department of Public Health, in which was compared the physical defects in 1,000 migratory and 1,000 resident children in the same area, it was found that, with the exception of those diseases caused by malnutrition, such defects varied only slightly.

While very few cases of actual starvation have been found, the majority of the migratory children receive a diet low not only in calories but also in vitamins and protective minerals. This is due to two conditions; first, the economic status of the family is such that during the major portion of the year only the bare essentials can be provided, and, second, mothers are unused to preparing and using the large variety of vegetables and fruits which are obtainable in this state. To aid in remedying the second condition, nutritionists have been placed in the field to work with nurses and physicians of the state health department. They are holding classes and giving individual instructions to migratory mothers in the preparation and use of the foodstuffs readily obtainable. Also they are helping them plan for their families balanced dietaries that will come within their financial range. During the last six months, and especially during the flood periods of the past winter, the Department of Agriculture, through the Farm Security Administration, has provided food grants and excess commodities for distribution to these malnourished families. It is believed that through these aids the nutrition of the migrant has been much improved.

A motor truck equipped with x-ray apparatus, doctors and nurses is maintained by the state health department. Children of migrants are given tuberculin tests, and x-ray examinations are provided for reactors. Thousands of such children have been examined but, unexpectedly, the incidence of tuberculosis in children of migrants is found to be no greater than in children of local residents.

About three years ago the Resettlement Administration of the Department of Agriculture, later changed to the Farm Security Administration, began a camp building program to provide more adequate housing and sanitary facilities for these people. They are at present operating seven such camps in California. These provide wooden platforms on which to pitch tents, water supplies, facilities for garbage disposal and adequate sewerage systems. In some camps there are water-flushed toilets and shower baths, while in others pit privies of an acceptable type are used in place of water-flushed toilets. It was intended by the Farm Security Administration, at the beginning of its program, that these camps should not provide a permanent residence for all the migrants but should act rather as temporary accommodations for a small portion of the migratory population. It was intended that the gospel of adequate camp sanitation should be spread over as much of the population as possible. In line with this trend and with the help of local health departments a large number of the growers of the state have built new camps or reconditioned their existing camps to provide these facilities. In the central portion of the San Joaquin Valley large numbers of growers have not only equipped their camps for flush toilets, running water and garbage disposal facilities but have also built large numbers of one room houses for their employees. The trend has been to raise somewhat the standard of living of the migrant to accustom him to those sanitary accommodations that we regard as necessities.

The burden of hospital care and medical services soon became too great for any county to bear and such services were refused because of lack of legal residence. The Farm Security Administration and the California State Department of Public Health with the assistance

of the California Medical Association and the State Relief Administration organized, through funds provided by the federal government, the Agricultural Workers Health and Medical Association, a nonprofit corporation authorized under the laws of California, with three doctors of medicine serving on its board of directors. Through this association, patients who are cleared through field doctors and nurses under supervision of the state health department may be placed in private hospitals and receive private medical care at no cost to themselves. This plan is a distinct innovation and is the only one of its kind that is in operation within the United States. In the course of their regular field duties in public health service, such as provision of sanitation, communicable disease control and immunization, the doctors and nurses employed by the state or local health departments discover cases in which hospitalization and medical care are needed. Such patients have not acquired legal residence and are not eligible to admission to county hospitals. They are referred to the Agricultural Workers Health and Medical Association, which provides a list of private physicians whose services are available. From this list a practitioner of medicine is selected by the patient and, if necessary, a hospital of choice may be entered. Both hospital and physician are paid by the association, their fees being based on definite schedules approved by medical and hospital associations.

By this plan it is hoped that no migratory worker who is sick need go without medical care and, if needed, he may be provided with hospital and nursing services, without expense to himself. In this manner, local communities are relieved of an unfair financial burden and private physicians and hospitals are compensated for the essential services rendered by them.

There are no laws, federal or state, that would prevent the migration of any legal resident of any state into another commonwealth. California has received this army of migrants, and has provided for its health and welfare to the maximum of its ability. It expects the states of the Middle West to care for their own underprivileged citizens so far as possible and accepts the overflow with a feeling of responsibility. With federal assistance and with the cooperation of medical, welfare, education, relief and public health workers this gigantic task in the provision of aid for an army of the country's migratory workers can be completed and maintained. It means the amalgamation of a new type of citizen into the social structure of California and the development of a new consciousness of public responsibility in the solution of a national problem.

SUMMARY

1. In 1936 and 1937, approximately 100,000 individuals seeking manual labor entered California by automobile each year, nearly 260,000 having arrived in two and one-half years.

2. More than 57 per cent of these migratory laborers came from the Southern Middle Western states of Oklahoma, Texas, Arkansas, Missouri, Kansas and Arizona.

3. California, in cooperation with federal agencies, has controlled communicable diseases among these groups, no major epidemics having occurred.

4. Services included child and maternal hygiene, diagnosis of tuberculosis, public health nursing, educa-

tion in nutrition, including selection and preparation of proper foods, provision of housing facilities and general public health services.

5. Study of conditions among these laborers revealed their greatest need—that of education in the hygiene of proper living.

6. The amalgamation of this army of underprivileged people into the social life of California requires the coordinated efforts of social welfare, relief, medical, nursing, public health and administrative workers among local, state and federal agencies.

7. In public health administration there are no state border lines so far as migration is concerned and no direct effort can be made forcibly to bar entrance of migrants into California.

8. In administering public activities to control these migrant groups, full recognition, first of all, was given to their status as human beings and, with public health as a driving force, provision was made not for prevention of disease alone but for medical and nursing care, relief and housing facilities.

313 State Building.

ABSTRACT OF DISCUSSION

DR. MYRNIE A. GIFFORD, Bakersfield, Calif.: The health problems of the migrant are largely those resulting from an inability to earn sufficient income to pay for adequate housing, food and sanitation. The feeling of insecurity resulting from the unsteadiness of available work in agricultural crops causes many functional body complaints, which are in reality the body's reactions to the fear under which many of the workers live. The Special Senate Committee to Investigate Unemployment and Relief found that the average earnings of the agricultural worker families in eleven representative counties was \$265 a year and that they were not indigents, because less than 2 per cent of their average incomes came from relief. The cost of a minimum adequate food supply for a family of five at \$6 a week for fifty-two weeks amounts to \$312 a year. This provides a meager amount of food. The minimum estimated cost to these families for traveling in getting from one job to another is \$125 for gas and oil. One wonders how they manage as well as they do. These figures explain why they live below the general subsistence living standard. Four times the number of agricultural workers are needed in harvesting seasons in California as are needed during the slack periods. Apparently there was not more tuberculosis, syphilis or other communicable disease among the migrant workers and their families than in the resident population of Kern County in 1937. There has been a significant relationship between the increase in the cotton industry in Kern County and the increase in the migrant population as well as the increase in the infant mortality in Kern County and admissions to the Kern General Hospital Service.

DR. A. T. McCORMACK, Louisville, Ky.: I have never heard a report which showed more effectively the usefulness of modern science in the development and preservation of modern civilization. The report raises a challenge to every one of us. Why did these migrant workers come to California undernourished? They were undernourished back home. Exactly the same problems surrounded them in the cabins they left as surround them now in the camps at which they have arrived. We did nothing about it there and I am wondering why. The situation, it seems to me, constitutes a challenge to the rest of us to do something about this class of people. We have them in my state and you have them in yours. The only difference between Dr. Dickie's case and ours is that Dr. Dickie knows the situation.

DR. MARY C. BALDWIN, Riverside, Calif.: I represent a slightly different element in this discussion from the majority of this section. I represent the private practitioners, and I was recently appointed to the county board of public welfare

in Riverside County. In a recent tour that we made of the county to look into welfare situations, we had the pleasure of visiting one of the federal camps that Dr. Dickie has described. The nurse on the job told us of the conditions there with some 800 inhabitants in the camp on the day we visited it. It was immaculately clean. It was an interesting experiment in giving these people, for the first time in their lives, probably, a chance to have a bath under a shower. The nurse was doing a tremendous piece of health education work. She had literature in a little waiting room on all the subjects we want people to know about: syphilis, maternal health, all that sort of thing, and she said the publications were being avidly read. Dr. Gifford's point about their apprehension is well taken. There they have houses that are kept clean and an electric washing machine to every forty families. I have just one plea to leave with you from the standpoint of a private practitioner. We see these people in our offices as private patients. We wish more could be done for them. We wish that more active communication could be established between your group and our group. We could do a lot to help you and you could do a lot to help us, and we are anxious to be of every help that is possible. I think Riverside County is the front door for these migrants; most of them come in through Blythe. I wish we might have a more active feeling of leadership from your group. Our group is really very willing to help.

DR. PETER COHEN, Santa Maria, Calif.: All of us doing any kind of public health work have come in contact with this problem in California. In the northern end of Santa Barbara County there is a large acreage of peas, and in the early spring months we are invaded by a horde of people to pick peas. This past season was an unfortunate one, at least at the beginning, for the pea crop. As the result of weather conditions, the peas were not quite ready for picking when the migrant workers came in and we had several hundred on our hands for some time before work was available. These people were in our county during March and April, and during that time a number of persons from this group were admitted to the local county hospital in the northern end of the county. During those two months 20 per cent of the admissions were from this migratory group and that included cases of smallpox, typhoid and some of the other communicable diseases as well as fractures. Incidentally there were two cases of smallpox, which were the first cases that we have had in Santa Barbara County for many years. In connection with the tuberculosis mobile unit, we had occasion to make use of those facilities too. Eighty-seven persons in the camps were examined by the mobile unit and four active cases of tuberculosis were found, which I think is much higher than has been found in other camps. There was one incipient case, one moderately advanced, and two far advanced. It is gratifying to know that this state has taken such a forward step in taking care of these people, who are attempting to better their lot, and I think California has certainly shown the way.

DR. W. M. DICKIE, Berkeley, Calif.: I should like to impress on everybody that practically all these people are old American stock and to a large extent they are replacing our foreign laborers. Another thing, in our work we have done 83,000 typhoid vaccinations and have vaccinated thousands of these people for smallpox. We intend, as long as they are moving around the state, that we shall continue our immunization program not only for their protection but for the protection of the people of the state as a whole.

Sanitation in Rome in the Second Century.—Lanciani gives us a vivid picture of the sanitation of Rome in the second century, when the city had 800,000 inhabitants. The drinking water was contaminated, the sewers were clogged, and the burial of the poor was in great public pits along with the refuse and garbage of the inhabitants. He calculated that one pit, uncovered after two thousand years, must have contained 6,400 bodies, the odor from which was "still a horrible stench."—Hurd-Mead, Kate Campbell: *A History of Women in Medicine*, Haddam, Conn., the Haddam Press, 1938.

AN EXPERIMENTAL STUDY OF THE BEHAVIOR OF SULFANILAMIDE

FRED L. ADAIR, M.D.

H. CLOSE HESSELTINE, M.D.

AND

LUCILE R. HAC, Ph.D.

CHICAGO

The obstetrician and gynecologist is rarely confronted with more serious infections than those caused by the gonococcus and the hemolytic streptococcus. Since its introduction in 1935, sulfanilamide¹ has been used in the treatment of these infections, but not always with favorable results and sometimes with untoward consequences. In sepsis due to the hemolytic streptococcus, the death rate is so high that drastic though hazardous therapy is sometimes justifiable. Gonococcal infection, although frequently associated with serious or incapacitating complications, rarely causes death; so until further studies have been made, routine use of this therapy which may produce dangerous reactions is unwarranted.

Some time ago this investigation was undertaken in order to determine the efficacy of sulfanilamide therapy

TABLE 1.—Time Required for Smears and Cultures to Become Negative

Patients	Number of Days Required for		Difference in Days for Any One
	Negative Smears	Negative Cultures	
1-10	0-35	8-35	0-8

12	5	56	51

* Positive smear was never obtained.

on gonorrhea of the female. The treatment of gynecologic and obstetric patients presented certain problems not previously encountered in the administration of the drug, namely:

1. The elimination of the drug in certain body fluids: cervical secretion, menstrual fluid, and human milk.
2. Its transmission to and its effect on the unborn fetus.

This paper is a preliminary report of some of the observations made in the study of these problems.

The treatment of gonorrhea with sulfanilamide has been carefully controlled by detailed studies of the blood changes, blood level of the drug, and its urinary excretion. The criterion of cure has been based on the absence of the gonococcus in both culture and smear. Only twelve patients have been studied in this detail. Conclusions, of course, cannot be drawn from such a small number, but cultural methods for determination of cure seem to have positive advantages.

Table 1 shows the number of days required after the institution of sulfanilamide therapy before both smears and cultures became negative. In no case were the smears positive after the cultures had become negative.

This work has been done under a grant from the Albert B. Kupperheimer Foundation.

From the Department of Obstetrics and Gynecology, the University of Chicago, and the Chicago Lying-In Hospital.

Read before the Section on Obstetrics and Gynecology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

(Mme.); Nitti, F., and Bovet, D.: Activité du p-aminophénylsulfamide sur les infections streptococciques expérimentales de la souris et du lapin, *Compt. rend. Soc. de biol.* 120: 756, 1935.

Usually the smears were negative before the cultures, though generally the variation was not greater than eight days. Patients 11 and 12, however, showed a difference of thirty-six and fifty-one days respectively. Without cultures, the clinical appearance and smears in these two cases might have led to premature conclusions relative to cure. The advantage of cultures has not been overestimated and they should be employed whenever possible.

It has been fairly well established that sulfanilamide is evenly distributed throughout the body.² Its presence in cervical secretion might be assumed and could explain its curative value in gonorrhea. Cervical secretion was collected in vaginal diaphragms and by pipets and analyzed for the presence of the drug. It was found in the secretion, but in such small percentages that its bacteriostatic or bactericidal action could be questioned.

The drug was found in menstrual blood in appreciably greater proportion than in the cervical secretions.

It is of considerable importance to know whether nursing mothers excrete sulfanilamide in their milk. Studies of methods for the determination of the amount of sulfanilamide in the milk of lactating women were begun some time ago. While this work was in progress, Bauer and Gunderson³ reported the effect of sulfanilamide on streptococcic mastitis in cows and stated that the amount of drug excreted in the cow's milk could be determined by a modification of Fuller's method for blood. Hepburn, Paxon and Rogers⁴ found sulfanilamide in the milk of sixteen puerperal women. The concentrations varied from 0.55 to 2.17 mg. per hundred cubic centimeters twenty-four hours after its initial administration. No procedure for analysis was given.

We have used a modification of Marshall's⁵ method for blood. In brief, the method was as follows: To 5 cc. of milk in a centrifuge tube was added 2.5 cc. of a 20 per cent solution of *p*-toluenesulfonic acid. The solutions were mixed, allowed to stand overnight at room temperature and then centrifuged. If the cream rose to

Chart 1.—Comparison of milk and blood levels: Two Gm. (30 grains) of sulfanilamide administered in two doses four hours apart. Solid line, milk; broken line, blood.

the top, it was necessary to follow centrifugation by filtration. Occasionally at this point there was a slight turbidity which made accurate colorimetric determinations impossible. This turbidity could usually be cleared by a drop or two of acid.

Three cc. of the clear supernatant liquid or of the filtrate was pipetted into a flask and diluted with 8 cc.

of distilled water, i. e. a 1:5 dilution of milk. The *pH* of this solution was about 1.0, which seems to be the optimal acidity for the coupling reaction. To the solution was added 1 cc. of a 0.1 per cent solution of sodium nitrite. After three minutes, 5 cc. of a solution of dimethyl *a* naphthylamine (1 cc. in 250 cc. of 95 per cent ethyl alcohol) was added, and the color was compared with a suitable standard. Ordinary breast milk to which definite concentrations of sulfanilamide have been added can be treated in the manner just described and used as a standard. Ten cc. of a standard aqueous solution to which 1 cc. of *p*-toluenesulfonic acid has

Chart 2.—Comparison of milk and blood levels: Four Gm. (60 grains) of sulfanilamide administered in two doses four hours apart. Solid line, milk; broken line, blood.

been added may also serve as a colorimetric standard, but the solution which has contained milk tends to give a more exact color match.

Perhaps it should be mentioned again that this diazotization and coupling reaction is a general reaction characteristic of all aromatic amines and not a specific one for sulfanilamide. For that reason, controls were run on samples of milk obtained from each patient just before the drug was given. No false positive reactions were observed.

The patients were in the fourth to the tenth postpartum day and received orally a total of 2 or 4 Gm. (30 or 60 grains) of sulfanilamide in two equal four hourly doses. Alternate breasts were emptied by an electric breast pump at intervals of four hours. Whenever possible, blood was taken just before the breasts were pumped; the milk and blood levels were compared and the total amount of drug excreted in the urine was determined. The accompanying graphs show the results obtained with two typical patients who received 2 and 4 Gm. doses, respectively.

Two groups of ten patients each received 2 and 4 Gm. doses, respectively, of sulfanilamide. Tables 2 and 3 show the amounts of drug excreted daily for the three days following the administration of the drug.

Sulfanilamide was excreted in the milk as in the urine, partly unchanged and partly as the conjugated acetyl form. This may be of some importance since it has been shown that in animals the toxicity of acetyl sulfanilamide is somewhat greater than that of the free sulfanilamide.⁶

Of the ten patients who received 2 Gm. doses, the total amount of drug excreted in the milk varied from 3.76 to 13.67 mg.; of those who received 4 Gm. doses, the variation was from 11.77 to 54.00 mg. In terms of milligrams per cubic centimeter the variation was from 0.006 to 0.016 and from 0.019 to 0.040 mg. per cubic centimeter respectively. The amount of drug excreted does not seem to be related to the total milk volume.

Some patients, whose urinary excretion of sulfanilamide was poor, eliminated proportionately larger amounts of the drug in the milk.

The milk levels were higher than the blood levels from the time the first specimens were collected, four hours after initial medication, and sulfanilamide continued to be excreted in the milk even after the blood levels had become negligible. In the patients who

received 4 Gm. of drug, the blood level dropped at the end of twenty-four hours to about 1 mg. per hundred cubic centimeters, while the milk level was still from 4.2 to 8.8 mg. per hundred cubic centimeters. It was still above 1.0 at the end of forty hours and in some cases it was as high as 1.4 mg. per hundred cubic centimeters even after sixty hours.

The appreciable differences in blood and milk levels during the first forty-eight hours require some explanation, even though these differences may not be so great as the graphs might lead one to believe. The milk and blood specimens were collected at the same time, but it must not be assumed that the time relationship of the levels is absolute. The blood level is momentary, while the milk level represents a cumulation level of the normal and abnormal constituents excreted during the previous four hours. The continued excretion of the drug in the milk after the blood levels were negligibly low seems to indicate that there is some concentration of the drug in the mammary glands. We have no proof to offer but suggest that the materials taken from the blood stream circulating through the breast to form milk may have an affinity for sulfanilamide. These substances accumulate in the breast and are ultimately excreted in the milk rather slowly, so that there is a period of retention.

From 60 to 75 per cent of the sulfanilamide can be accounted for in the urine, where it seems to be excreted more rapidly than in the milk. Little or no drug was found in the urine after forty-eight hours.

The largest amount of drug excreted in the milk was only 1.5 per cent of that administered. With a double dose of drug, considerably more than a double amount was excreted in the milk. Whether or not prolonged use would result in an accumulation of the drug in the milk cannot be answered at this time.

Hoffman, Schneider, Blatt, Herrold and others⁷ have shown that young children tolerate the drug quite well. The tolerance of the newborn is unknown; therefore it would seem safer to discontinue breast feeding during the period of the presence of sulfanilamide in the milk.

7. Hoffman, S. J.; Schneider, Maurice; Blatt, M. L., and Herrold, R. D.: Sulfanilamide in the Treatment of Gonorrheal Vulvovaginitis, *J. A. M. A.* **110**:1541 (May 7) 1938. Symposium on Sulfanilamide Therapy, *J. Pediat.* **11**:156 (Aug.) 1937.

The rabbit was the animal chosen for the study of the effect of sulfanilamide⁸ on the fetus. Pregnant rabbits tolerate handling better than rats or mice, and their period of gestation is relatively short. In the rabbit, as in man, the drug is partly acetylated in the body and excreted in the conjugated acetyl, as well as the unchanged form. In the dog, acetylation does not seem to take place.²

The toxicity of single doses of sulfanilamide has been fairly well determined for the rabbit. Raiziss, Severac and Moetsch⁹ showed that 94 per cent of their rabbits tolerated oral administration of 1.5 Gm. per kilogram; 50 per cent tolerated 2 Gm. per kilogram. Halpern and Mayer¹⁰ stated that the toxic dose for rabbits was 2 Gm. per kilogram. Almost no work has been done on the toxicity of the drug when it is administered over a prolonged period. Marshall, Cutting and Emerson⁶ reported that deaths occurred in two rabbits that had received 3.5 Gm. per kilogram of sulfanilamide within two days, but no ill effects were observed in two rabbits which had received 4 Gm. per kilogram within four days.

It seemed best in a study of this type to determine first the effect during pregnancy of large but sublethal doses of the drug and then to decrease the dosage in subsequent groups as necessary. The first group of twenty animals received 0.5 Gm. per kilogram, an amount, of course, proportionately very large in comparison with the dose administered to man but one which was believed to be well within the toxic limits for the rabbit, since a group of five nonpregnant rabbits received the dosage with little effect other than a slight loss of appetite. The second group of twenty and a third group now being studied received 0.25 Gm. and 0.10 Gm. per kilogram, respectively.

Rabbits were obtained from reliable rabbitries, in groups of four, all bred on the same day. They varied in size from 2.5 to 6.5 Kg., but most of them were between 4 and 5 Kg. Two, and later one, of each group of four were used as controls. The controls, eleven in all, were handled and manipulated in exactly the same manner as the test rabbits, but they received no drug.

At first the sulfanilamide was fed in tablets or in acacia suspension, but later gelatin capsules were used exclusively. The rabbit was held by the back of the neck and hind legs in a half sitting position, and the capsules, which had been moistened in water, were placed in the pharynx. No mouth gag of any kind

8. The crystalline prontosil used in this investigation was supplied through the courtesy of the Department of Medical Research, Winthrop Chemical Company, Inc.

was used; thus struggling and handling were reduced to a minimum. Medication, once a day, was begun on the twenty-third day of pregnancy, i. e., eight days before the due date, and was continued until the young were born.

During the experiments there were seven deaths (11 per cent) among the test rabbits and one (7 per cent) in the controls. Of the test rabbits three died before delivery, two during delivery and two on the third day after delivery. Three of the deaths were due to causes not attributable to the drug; the other four may or may not have been due to individual susceptibility. The organs of the animals that died after delivery contained no sulfanilamide.

Fifty per cent of the controls lost from 200 to 600 Gm. each in weight. Of those that received 0.5 Gm. per kilogram, 86 per cent lost from 200 to 600 Gm. each. Most of these animals appeared somewhat toxic and lost appetite. Some of the rabbits received a small amount of a solution of sodium bicarbonate after their capsules, but with no apparent beneficial results.

One of the young from each litter was killed as soon after birth as possible. Portions of the liver, lungs, kidney and brain were examined for pathologic changes, and the rest analyzed for sulfanilamide content. The drug was found in the blood, urine and organs of all the

All the rabbits listed in table 4 were housed in individual large cages, which were provided with nest boxes. At the beginning of this work, however, the experiments were carried out with rabbits (twenty-two in all) housed in ordinary small rabbit cages. In this series, in which conditions were less favorable for growth, not a single young born of fifteen test rabbits survived; twelve, or 23 per cent, of the fifty-one young born of seven control rabbits did survive. It would seem, therefore, that sulfanilamide diminishes the chances of survival of the young, and particularly so if conditions are unfavorable.

Although the rabbit excretes the drug in the same form as man, one cannot be certain that its absorption and utilization are the same. We have, however, established the fact that the drug is transmitted to the human fetus. Three patients received 1 Gm. each of sulfanilamide from three to six hours before delivery. The drug was found in the placenta and cord blood in all three cases.

CONCLUSIONS

1. Sulfanilamide has been found in the cervical secretion and menstrual fluid, but in amounts so small that its bactericidal action on the gonococcus is questionable.

The criterion of cure of gonorrhea should be based, if possible, on cultural studies as well as smears.

2. Sulfanilamide is excreted in breast milk, both free and as the acetyl derivative. The milk level is considerably above the blood level, and the drug is excreted in the milk for some time after the blood level is negligibly low. With doses of 2 and 4 Gm. (30 and 60 grains) the total amount excreted was never greater than 1.5 per cent of the amount of the drug administered. It was still being excreted in small amounts seventy-two hours after medication had been discontinued.

3. Sulfanilamide is transmitted to the placenta and fetus of the rabbit and is associated with a marked increase in the mortality of the young. Sulfanilamide has also been found in the placenta and cord blood of the human being.

4. Until more is known of the tolerance of the human fetus and of the newborn for sulfanilamide, the drug should be administered only with the utmost caution during pregnancy and the period of lactation. If administered to the mother, breast feeding should be discontinued during the period that sulfanilamide is excreted in the milk.

ABSTRACT OF DISCUSSION

DR. HERBERT O. CALVERY, Washington, D. C.: Sulfanilamide is partially acetylated in man and most other animals, the dog being the exception so far as is known. In their summary the authors discussed a question as to whether or not the toxicity referred to might be due to the acetyl derivative; as a matter of fact, they did not answer that but did state that the acetyl derivative is always excreted in the milk. I wonder whether they found the acetyl derivative in vaginal secretions and whether or not the effect of sulfanilamide on the fetus was due to the toxicity of the acetyl derivative, which is more toxic than the free sulfanilamide, or whether they think that was due to the sulfanilamide itself. The authors pointed out that the administration of this substance to pregnant animals is hazardous and should be undertaken with caution. I cannot help raising the question concerning the high mortality among their controls which they probably have already partially answered by stating that they had trouble with caging. Because of the loss of weight and high mortality among the control

* Fetal and neonatal deaths, but not those killed for the experiment.

stillborn and killed young from test animals. There were no false positive reactions in the young from controls.

In one case the drug was fed for eight days and then discontinued. The rabbit kindled three days later. No drug was found in the blood or urine of the young that were killed, but it was present in the liver.

After the third day the size of the large litters was decreased to seven; the young above that number were killed or, if possible, transferred to other does. Whenever transfers were made from control rabbits to test rabbits, the growth of the young fed by the test rabbit was much slower than that of those fed by the control. The does and young were observed for eight days and then returned to the rabbitries.

In table 4 the mortality of the young born of test and control animals is compared.

When sulfanilamide in amounts well within the tolerance dose was fed to pregnant rabbits, the drug was transmitted to the circulatory system of the fetus and was associated with a marked increase in the mortality of the young. When the dose was decreased from 0.5 Gm. per kilogram to 0.25 Gm. per kilogram, the effect of the drug was still evident but it was not nearly so pronounced. In addition to the increased mortality, the drug seemed to alter the time of delivery. Forty per cent of the animals that received 0.5 Gm. per kilogram of the drug kindled from three to five days before their due date.

animals it seemed to me that some other factor might be operating as well as the sulfanilamide. Such experiments as these are highly commendable types of investigations. I think pharmacologists should be chided for the negligence they have shown in failure to investigate thoroughly the toxicity and pharmacology of a compound of such clinical significance as this one. Probably most physicians know that sulfanilamide was used in the clinic even before it was ever investigated on animals at all, and it is my feeling that this should not be the case. It is probably unfair to ask the authors to carry out pharmacologic experiments when they have many other things they would prefer to do, but I think they feel that the pharmacologic tests should by all means be made, and since this information was not available on this point, they have made it so.

DR. J. P. PRATT, Detroit: Recently Dr. H. L. Steward and I have been interested in the excretion of sulfanilamide in human milk. Twenty-eight cases have been studied for the concentration of the compound in blood and milk. Our method of administration differs slightly from the authors' but the results obtained are comparable. They divided the total administration into two doses for one day, while we gave the same total daily amount of 30 or 60 grains (2 or 4 Gm.) in 5 or 10 grain (0.3 or 0.65 Gm.) doses every four hours day and night at nursing time. Milk was taken with the breast pump immediately before the feeding, the accumulated excretion thus being sampled during each four hours. Ten patients received 30 grains (2 Gm.) daily, while eighteen received 60 grains (4 Gm.). They gave sulfanilamide only one day but followed the excretion for several days. We gave the drug daily for seven days and followed the excretion. Allowing for the differences in administration, our results are nearly parallel. We do not share the authors' conclusion that "if administered to the mother, breast-feeding should be discontinued during the period that sulfanilamide is excreted in the milk." They show that the highest total excretion in the first day is only 32.5 mg., or about one-half grain. While there is no established dose for newborn babies, Long and Bliss (*Ann. Int. Med.* 11:575 [Oct.] 1937) state that they should receive a total of 1,000 mg., or 15 grains, for 10 pounds of body weight during the first twenty-four hours. By the administration of 60 grains to the mother, the authors' figures indicate that a nursing baby would receive only one thirtieth of the dose suggested by Long and Bliss. A full dose for the baby would therefore call for thirty times 32.5 mg., the highest daily excretion in milk reported by Dr. Adair and his co-workers, or 975 mg. To attain such a level is not practical. We have found that, among the twenty-eight nursing babies whose mothers were receiving sulfanilamide, not one showed any clinical signs of toxicity. In the blood of eight babies we found only traces which were too small to measure. The total twenty-four hour urine from six of the eight babies showed only from 1 to 3 mg. per hundred cubic centimeters. The authors have drawn conclusions by inference from animals which do not seem to be in accord with the clinical data. There is no apparent danger of toxicity to a baby nursing from a mother receiving therapeutic doses. Conversely, it is not an adequate therapeutic means of administering sulfanilamide to the nursing baby.

DR. E. D. PLASS, Iowa City: It is not the function of the Chair to discuss, but I would like to ask the authors how they explain the fact that the mammary gland excretion of sulfanilamide continues after the sulfanilamide has disappeared, apparently, from the blood stream.

DR. H. CLOSE HESSELTINE, Chicago: In choosing the amount for the rabbits we tried to take what we thought might be a maximum sublethal dose. We had to guess at that because there was not much information available for dosage continued over a period of days in these animals. We first started with 0.5 mg. per kilogram daily, beginning eight days before the expectant date of delivery. Then to evaluate smaller doses, the amount was changed to 0.25 mg. per kilogram and later to an even lower dosage. Dr. Calvery's question regarding the deaths of the bunnies in the controlled series is appreciated. When larger cages were used the rate decreased appreciably, while those from mothers receiving the drug did not change so much. The controlled series received no drug but had

identical handling and were given acacia, capsules, or tablets without the drug. For the present we disagree with Dr. Pratt as to the safety of nursing, as we do not know how much of the drug will appear in the milk over a period of days with full dosage. In the future, evaluations will be made on the blood levels and milk excretion after three or four days' therapy and then it may be seen whether it is still higher than after one or two doses. This reason alone makes us skeptical. As to the question from the Chair, we do not yet know why sulfanilamide is excreted in the milk for hours after it had appreciably or practically disappeared from the blood. Controlled analyses have repeatedly shown this fact and we believe that this will be easily confirmed by others. For the present we might assume that the breast tissue is capable of picking up the drug, holding it, and then excreting it over a period of hours or perhaps days.

THERAPEUTIC EFFECTIVENESS AND TOXICITY OF SULFANILAMIDE

AND SEVERAL RELATED COMPOUNDS: FURTHER CLINICAL OBSERVATIONS

EDWARD G. BANNICK, M.D.
SEATTLE

ALEX E. BROWN, M.D.
ROCHESTER, MINN.

AND
FRANK P. FOSTER, M.D.
MONTCLAIR, N. J.

In a previous paper we¹ expressed our belief in the efficacy of sulfanilamide in the treatment of infections due to hemolytic streptococci, meningococci, gonococci and organisms causative of infections of the urinary tract with the exception of *Streptococcus faecalis*.

Our present report deals briefly with our further experience with sulfanilamide and with our use of other sulfonamide preparations. It includes a review of oral administration of two allied preparations, di-methyl-di-sulfanilamide (di-septal, Uliron, DB90, D373) and neoprontosil (prontosil soluble). A preliminary review also is given of treatment of chronic ulcerative colitis with preparations of the type of those just named.

SULFANILAMIDE

Since our first report greater experience with sulfanilamide has enabled us to confirm our early impressions of its therapeutic value, limitations and dangers. With the passage of time we have strengthened our belief in the value of this drug in the treatment of infections mentioned in the opening paragraph. We have not had sufficient experience to allow us to form any definite opinion regarding its true worth in treatment of infections with pneumococci. Results obtained with specific serum, however, should make use of such serum the treatment of choice for infections with pneumococci, although experimental work² indicates the wisdom of the combination of specific serum and sulfanilamide in selected cases, and the use of sulfanilamide alone when serum therapy is not available or when the disease is of considerable duration.

From the Division of Medicine, University of Washington Clinic, and Therapeutics at the Eighty-Ninth Annual Meeting of the American Medical Association, San Francisco, June 17, 1938.

2. Branham, Sara E.: *Studies in Chemotherapy: V. Sulfanilamide, Serum and Combined Drug and Serum Therapy in Experimental Meningococcus and Pneumococcus Infections in Mice*, Pub. Health Rep. 52: 685-695 (May 28) 1937. Osgood, E. E.: Personal communication to the authors.

Our experience with sulfanilamide thus far has demonstrated a lack of satisfactory results in treating infections with *Staphylococcus aureus*, *Staphylococcus albus* and *Streptococcus viridans*. We have had varying results in treatment of several cases of undulant fever, and in one case of tularemia we noted no benefit from sulfanilamide. The results of our treatment of rheumatic fever have paralleled those reported by Swift³ and have been unsatisfactory in general, just as have been those obtained in the treatment of infectious arthritis and fibrositis. The course of two cases of severe infectious mononucleosis appeared to be shortened when sulfanilamide was used.

Our experience has led us to feel that the optimal dosage of sulfanilamide is as yet unsettled. We believe that this depends chiefly on the type and severity of the infection. Long's⁴ studies indicating the value of a concentration of the drug of 10 mg. per hundred cubic centimeters of blood have caused us to believe that this is a favorable concentration to obtain in fulminant cases. A concentration in the blood approaching this should be attained early and maintained until clinical improvement occurs or until symptoms of toxicity necessitate its reduction. Recently Long has advocated even higher concentrations in such cases. In the moderate and mild infections and in most patients with gonorrhea a concentration of sulfanilamide in the blood of from 5 to 7 mg. per hundred cubic centimeters seems to be adequate and this frequently can be obtained in adults with daily doses of from 4 to 5 Gm. In most infections of the urinary tract, daily doses of from 3 to 4 Gm. of sulfanilamide produce a concentration of sulfanilamide in the blood of from 3 to 4 mg. per hundred cubic centimeters, which seems to produce satisfactory results and the results seem to be definitely enhanced if the urine is alkaline. The recent experimental work of Osgood⁵ tends to show the value of small doses of the drug and yet our clinical experience has seemed to indicate the value of comparatively large doses at least during the early part of the treatment. However, we have not had sufficient experience with small doses properly to evaluate their effect. Uniform intervals between doses within each twenty-four hours seem essential to maintain satisfactory concentration in the blood for the production of optimal results.

The toxic manifestations which appear in the course of treatment with sulfanilamide seem to occur on a basis of sensitivity and idiosyncrasy. The latter, while apparently rare, is serious and the former, while more common, is usually mild but may become serious if ignored. Most individuals seem to exhibit some sensitivity when the initial doses of the drug are large or when the total administered amount is considerable. The toxic manifestations which occur with such doses are usually mild and consist largely of malaise, anorexia, nausea, vertigo and tinnitus. With continued use of the drug, these symptoms may be followed by cyanosis attributable to methemoglobinemia, sulfhemoglobinemia or the presence of an unidentified substance in the blood; abdominal cramps, diarrhea, cutaneous lesions, fever, paresthesias and so on also may supervene. When these mild to moderate toxic symptoms occur

we believe they should be considered seriously, for they may herald the advent of more serious complications such as leukopenia, granulocytopenia, anemia of acute type or associated with crisis, jaundice and a state resembling shock. Persistence and increase of these mild to moderate symptoms, in spite of decrease in dosage of the drug, constitute ample reasons for discontinuance of its administration, particularly if the preparation is used as a more or less optional measure. If after several days a further attempt is made to use the drug and these symptoms again arise and tend to persist, we believe that administration should be permanently discontinued and some other form of treatment used. We also believe that the blood offers an index of toxicity even more important than the symptoms and that decrease in the hemoglobin content or in the erythrocyte count or leukocyte count must be taken as evidence of a dangerous complication which necessitates immediate discontinuance of this form of therapy.

The likelihood of occurrence of the foregoing toxic manifestations is increased in the presence of existing marked anemia, leukopenia, and renal and hepatic damage. The presence of any of these conditions, therefore, constitutes a contraindication to the use of sulfanilamide. If, under certain circumstances, it seems advisable to use the drug in spite of the presence of contraindications, it must be given with caution. We have seen no fatalities from blood dyscrasia following use of this preparation. Jaundice following the use of sulfanilamide has been noted in two cases in which death occurred and in which it is possible that hepatic damage existed prior to the beginning of the treatment. We have felt, as a result of this experience, that sulfanilamide may cause hepatic damage which already exists to progress to a stage from which regeneration is impossible. In contrast to this complication are the mild attacks of jaundice which occasionally are seen and which usually subside rapidly when use of the drug is discontinued and intake of fluids is forced. These two measures are of extreme importance in combating toxemia from sulfanilamide and may be reinforced by the use of transfusions of blood or oral administration of bone marrow when disturbances in the blood occur.

Fortified by a knowledge of the nature of the toxic manifestations of sulfanilamide, we believe that constant observation of the patient under treatment will allow detection of these abnormal reactions when they are still amenable to appropriate measures and will prevent the occurrence of fatalities save in rare instances.

DI-METHYL-DI-SULFANILAMIDE

In view of available reports,⁶ we felt that clinical work with di-methyl-di-sulfanilamide was justifiable. From September to December 1937, di-methyl-di-sulf-

anilamide was used at the Mayo Clinic in treatment of approximately seventy patients. Of this group, thirty-two were seen by us in the general medical services and form the major basis of this report; the remaining thirty-eight were seen by our colleagues of the Section on Urology.

This series of thirty-two patients represented infections with anaerobic streptococci, hemolytic streptococci, *Streptococcus viridans*, *Staphylococcus aureus*, colon bacilli, *Proteus vulgaris*, gonococci, pneumococci and actinomycetes. Although small, this series offers some basis for comparison with a similar group of patients whom we have treated with sulfanilamide and therapeutically the results seem similar. Although the coincidental use of other therapeutic agents, such as roentgen rays or radium, in treatment of certain of these infections has made accurate evaluation of individual therapeutic measures difficult, nevertheless we have felt, in view of past experience, that many of the favorable results would not have occurred so promptly without the use of di-methyl-di-sulfanilamide.

The usual daily dose of this drug was 4 Gm., although at times daily doses up to 7 Gm. were given and the

for conjugated sulfanilamide when the daily dose was 4 Gm. When a similar daily dose of di-methyl-di-sulfanilamide was administered, urinary concentrations were 58 mg. per hundred cubic centimeters for free and 68 mg. per hundred cubic centimeters for conjugated di-methyl-di-sulfanilamide.

Of striking interest in this group of thirty-two cases in which di-methyl-di-sulfanilamide was given was the rarity of symptoms of toxicity. In passing it may be mentioned that lack of acute symptoms of toxicity was also noted in the thirty-eight cases seen by the urologists and not included as the basis of this report. Mild nausea and malaise occurred when three patients received a follow-up course of the drug in the treatment of an infection of the urinary tract. In one case of chronic ulcerative colitis during a secondary course of di-methyl-di-sulfanilamide, taken after the patient had left the clinic, there occurred fever, dermatitis and cyanosis, the last presumably due to methemoglobinemia. Also in one case of chronic osteomyelitis with septicemia, mild vertigo and tinnitus occurred.

In seven of the thirty-two cases the previous administration of sulfanilamide has been attended by various manifestations of toxicity which made further treatment with this drug inadvisable. In some instances as little as from 1 to 2 Gm. of sulfanilamide had repeatedly produced cyanosis (methemoglobinemia or sulfhemoglobinemia), malaise, emesis, dermatitis or high fever and yet the administration of di-methyl-di-sulfanilamide in therapeutic doses in these cases produced no clinical evidence of toxicity. In several instances, administration of di-methyl-di-sulfanilamide was begun while toxic effects of sulfanilamide were still present and in every such instance these toxic effects rapidly disappeared when administration of sulfanilamide was discontinued. Although there was evidence of clinical cyanosis in only one instance, nevertheless small amounts of methemoglobin could be detected spectroscopically in the blood of the majority of the patients who received 5 Gm. or more of di-methyl-di-sulfanilamide daily. In no instance was sulfhemoglobin detected in the blood.

Careful observation was made of the concentration of hemoglobin and careful erythrocyte and leukocyte counts were made, but no significant changes attributable to di-methyl-di-sulfanilamide were noted. Neither was there any decline in the carbon dioxide combining power of the plasma, such as has been noted with the use of sulfanilamide. Results of urinalysis also remained essentially negative.

Of the thirty-two cases, in twenty-two improvement was marked, in six no benefit resulted, in three improvement was temporary, and in one the result was questionable. Death of one patient who had actinomycosis and one who had subacute bacterial endocarditis did not seem attributable to the previous use of di-methyl-di-sulfanilamide. Inadequate amounts of di-methyl-di-sulfanilamide were administered to a patient who had *Staphylococcus aureus* septicemia and the course of the disease was unaltered.

In two cases the unusual complication of peripheral neuritis occurred. In each instance only the lower extremities were involved and the complication came on rather rapidly when large doses of di-methyl-di-sulfanilamide had been given for a period longer than fourteen days. However, in four other cases in which the drug had been given in comparable doses for similar periods this complication did not occur. In one instance

* Includes nine cases of chronic ulcerative colitis.

drug was administered orally in five or six divided doses. The total amount of di-methyl-di-sulfanilamide given varied from 96 Gm. in twenty-five days in one case to 8 Gm. in from two to three days in three cases.

The concentrations of di-methyl-di-sulfanilamide in the blood were estimated by the method of Marshall⁷ for determining sulfanilamide but a standard of di-methyl-di-sulfanilamide was used instead of one of sulfanilamide. This was done because it was thought that di-methyl-di-sulfanilamide did not form sulfanilamide in the process of metabolism. Hence the reaction product with di-methyl-naphthanine could be approximated more closely by a standard of di-methyl-di-sulfanilamide than by one of sulfanilamide. The results disclosed a much lower concentration of di-methyl-di-sulfanilamide in the blood than the concentration of sulfanilamide obtained when similar amounts of that drug were given. Concentrations of di-methyl-di-sulfanilamide in the blood averaging 1.9 mg. per hundred cubic centimeters were obtained with an average daily dose of 4 Gm. as compared with concentrations of from 4 to 7 mg. per hundred cubic centimeters of sulfanilamide when a similar dose of the latter drug was given. Urinary concentrations of sulfanilamide had averaged from 60 to 125 mg. per hundred cubic centimeters for free sulfanilamide and from 50 to 125 mg. per hundred cubic centimeters

7. Marshall, E. K., Jr.; Emerson, Kendall, Jr., and Cutting, W. C.: Para-Aminobenzene-Sulfonamide: Absorption and Excretion: Method of Determination in Urine and Blood, J. A. M. A. 108: 953-957 (March 20) 1937.

the peripheral neuritis was mild and largely disappeared within seven days, while in the other it was more marked and was accompanied by bilateral foot-drop. Improvement was slow in the latter case but recovery was well advanced after sixty days. In the meantime, other reports on the occurrence of peripheral neuritis, by Hofmann,⁸ Tietze,⁹ Hüllstrung,¹⁰ and Krause have appeared in the German literature and additional cases have occurred in this country. In some of these cases the upper extremities have been involved. In some instances recovery has remained questionable.

Although di-methyl-di-sulfanilamide has appeared in our experience to possess certain advantages over sulfanilamide largely from the standpoint of lessened toxicity, the fact that its use has been followed by peripheral neuritis has caused us to curtail its clinical application until such time as it may seem that this complication has been eliminated. Possibly supplementary use of vitamin B₁ will be of benefit in preventing peripheral neuritis.

Because of the limitation of clinical material at the time di-methyl-di-sulfanilamide was tried we were unable to come to any definite conclusions regarding its value in infections due to staphylococci and anaerobic streptococci. We also realize that the presentation of such a small series of cases does not permit entirely satisfactory conclusions concerning therapeutic efficiency in other infections but we do feel that this experience is of value and that further controlled clinical and experimental study with this drug is indicated.

NEOPRONTOSIL (PRONTOSIL SOLUBLE)

The toxicity of neoprontosil when used parenterally has been said by many workers¹¹ to be low, and data are available which have tended to support our belief that the drug when given orally might possess valuable therapeutic qualities.¹² Of particular importance in this regard are the experimental studies of Rosenthal¹³ and of Raiziss.¹⁴ The former has shown that the therapeutic effect of neoprontosil when given parenterally is probably considerably decreased because of the rapid elimination of from 85 to 95 per cent of the drug in the urine five hours after its administration. Raiziss¹⁴ has shown that the protection afforded experimentally infected animals when neoprontosil is given orally

approximates closely that obtained by the use of sulfanilamide; the protection afforded when neoprontosil is given parenterally is markedly less and at the end of twenty-eight days is less than one half of the protection given following oral administration.

Accordingly we undertook this clinical study. The drug¹⁵ was supplied to us both in tablets of 5 grains (0.3 Gm.) and in capsules. The effect of the two seemed the same, but the capsules offered the advantage that they did not stain the mouth and fingers and their use did away with the objection that the tablets might be insoluble.

Evidence that the drug is quickly absorbed from the gastrointestinal tract is afforded by the rapidity with which the urine becomes colored and by the appreciable quantities of sulfanilamide which appear in the blood and urine of both normal and sick persons within twenty-four hours. The lack of toxicity of neoprontosil and the small quantity of sulfanilamide it contains made it reasonable to try the drug in doses at least as large as those of sulfanilamide.

When we first used neoprontosil orally we did not feel justified in relying on it alone, since we did not

TABLE 2.—Neoprontosil: Age of Patients, Dose, Duration of Treatment, Chemical Examination of Blood

1. Ages of patients treated, range.....	13 to 83 years
2. Average dose per course of treatment.....	25.5 Gm.
3. Largest single dose per day.....	6 Gm.

5. Average duration of treatment.....	7 days
6. Longest duration of treatment.....	23 days
7. Average concentration of free sulfanilamide in blood.....	2.1 mg. per 100 cc.
8. Highest concentration of free sulfanilamide in blood.....	3.6 mg. per 100 cc.

actually know how effective it was; hence it was used in conjunction with sulfanilamide in certain cases. In addition, a considerable number of patients were treated with neoprontosil because they were intolerant of sulfanilamide.

We have given neoprontosil orally either alone or in conjunction with some other of the sulfonamide drugs to ninety-three patients (tables 1 and 2). The indications were the same as those for the use of sulfanilamide.

The most important figure in table 1 is that showing the low incidence of toxic reactions to the use of neoprontosil. The incidence of toxic symptoms from sulfanilamide, as noted in our experience and in the literature, is found to be far higher than that noted in this series from neoprontosil. Furthermore, ten cases were observed in which neoprontosil gave satisfactory therapeutic results after sulfanilamide had produced symptoms of toxicity. In three cases of chronic ulcerative colitis the results were similar, but these three cases are not included in table 1.

A rather large percentage of failures was noted. In no one of these cases, however, was an organism demonstrated on which any sulfonamide compound has so far been shown to be bactericidal. We felt that the trial of neoprontosil justified its use in attempted treatment of a variety of diseases which included infections due to staphylococci, *Streptococcus viridans* and tubercle bacilli even though sulfanilamide had been shown to be without effect against infection by these organisms.

In addition, Hodgkin's disease, periarteritis nodosa, thrombo-angiitis obliterans, infected pulmonary embolus and diffuse arteritis were uninfluenced by treatment with neoprontosil, as might be expected from previous experience with sulfanilamide.

The mild nature of the toxic manifestations attributable to neoprontosil deserves emphasis. Cyanosis, insufficient to hinder treatment, was detected in four cases. Gastrointestinal intolerance to the drug, evidenced by nausea, cramps and vomiting, forced discontinuance of use of the drug in four cases; of these, two patients also used alcohol at the same time, which appeared to accentuate the irritant effect of the neoprontosil. Only one patient, who suffered from chills, fever and vomiting, was acutely sick from the use of

study of morphology of the cells and determinations of hemoglobin have disclosed changes, they could be considered to be associated with the primary disease. Acidosis never has become manifest clinically and cutaneous lesions have not been detected.

Slight fatigue and vertigo were noted in several cases. The sense of fatigue was experienced chiefly by those patients who were not seriously sick and it did not constitute a severe annoyance. Mild symptoms of gastrointestinal irritability when present usually appeared within the first day of treatment and generally could be relieved by giving the drug when the stomach was relatively empty. Our routine now includes giving the drug one hour before meals. Vomiting occasionally develops near the third day of treatment, which may necessitate withdrawal of the drug. As with sulfanilamide, these manifestations tend to disappear if brief rest from treatment is allowed. We found it advisable to inform the patients of the red color which appears in the urine and occasionally in the stools.

The concentration of sulfanilamide in the blood of patients to whom neoprontosil was given orally varied from 1 to 3.6 mg. per hundred cubic centimeters. Although these figures are low, the recent work of Osgood⁶ and Brownlee indicates that this concentration of sulfanilamide may be therapeutically effective. The early clinical observations of the use of these compounds demonstrated therapeutic effectiveness with smaller doses of neoprontosil than were administered to the patients in this series of cases.

Conclusions cannot be drawn from so few cases but perhaps we may suggest that neoprontosil when given by mouth constitutes a fairly effective therapeutic agent associated with relatively little toxicity. Oral administration possesses advantages over parenteral administration because it affords the use of larger doses, which permit greater concentrations in the tissues and greater therapeutic effectiveness and because it can be easily given. Our experience suggests that its chief role may be in treatment of patients who are moderately or markedly intolerant of sulfanilamide even in smaller doses than are usually administered and who urgently need treatment with some other agent that is valuable in combating infection. However, warning must again be sounded concerning the possibility of the occurrence of the toxic manifestations already noted in the use of sulfanilamide. Moreover, the existence of toxic features peculiar to neoprontosil alone has not been disproved.

TREATMENT OF CHRONIC ULCERATIVE COLITIS WITH SULFANILAMIDE AND SIMILAR COMPOUNDS

This part of the paper is a preliminary report on the use of sulfanilamide, neoprontosil and di-methyl-disulfanilamide in the treatment of certain cases of chronic ulcerative colitis.

The first patient who was given this treatment (patient 1, table 3) had been troubled with chronic ulcerative colitis intermittently for six years in spite of intensive treatment with dietary measures, serum and vaccine. On the fourth day after treatment with sulfanilamide was started, a severe toxic reaction occurred and use of the drug was discontinued. Following this the patient noticed marked improvement in the symptoms of colitis; the number of stools was greatly reduced and they contained much less blood and pus. After five weeks of improvement her symptoms recurred but because several

† Indicates occurrence of peripheral neuritis.

the drug and recovery was immediate on discontinuing its use. Satisfactory results were noted in one case each of infection due to pneumococci of types 1, 2, 7 and 8.

Although we do not believe that neoprontosil is effective if sulfanilamide fails from the therapeutic point of view, nevertheless neoprontosil appears to be of importance as a substitute when sulfanilamide is not well tolerated. It is our clinical impression that the therapeutic effect of neoprontosil given orally is obtained more slowly than that of sulfanilamide given by the same route.

The demonstration of sulfanilamide in the blood of a large number of patients treated with neoprontosil suggests that toxic effects may be the same as those when sulfanilamide is used. The toxicity of neoprontosil, however, appears to be low. Urinalysis has revealed no evidence of renal damage or irritation. In most instances in which frequent counts of blood cells,

further attempts to use sulfanilamide were attended by prompt occurrence of toxic manifestations it was decided to try neoprontosil orally. The result was striking; within a week the patient was having one or two formed stools daily and the bleeding had practically disappeared. Since that time improvement has been maintained following repeated courses of treatment with neoprontosil. Proctoscopic examination on several previous occasions had disclosed lesions of chronic ulcerative colitis with moderate activity, but proctoscopic examination five weeks after treatment with neoprontosil had been started revealed that the ulcerative process was quiescent.

Although chronic ulcerative colitis often is characterized by spontaneous remissions, nevertheless we felt that the prompt subsidence of symptoms in this case suggested that the drugs used had been of benefit. This opinion was shared by Dr. Bargen, who had observed this patient with us and further trial in other cases was undertaken with his approval.

We have treated with sulfanilamide, neoprontosil or di-methyl-di-sulfanilamide twelve patients who had chronic ulcerative colitis. In each case the diagnosis was confirmed by proctoscopic examination. In eleven cases roentgenograms of the colon were made and in eight of these there was evidence of chronic ulcerative colitis above the rectosigmoid region. In nine cases the chronic ulcerative colitis was uncomplicated by other disease and these have been grouped together in table 3.

In each of these nine cases improvement was definite. In six of these nine cases (cases 1, 2, 4, 5, 6 and 9, table 3) improvement was so striking and so prompt as to leave little doubt as to the value of the drug used. About the fourth day after treatment had been started the patients noted marked reduction in the number of stools and in the amount of bleeding, and this improvement continued until the patient was having one or two formed stools daily without gross blood. There was a tendency to slight recurrence of symptoms when administration of the drugs was discontinued, but this again was promptly controlled as soon as treatment was resumed. Gradually the interval between courses of treatment was lengthened without resulting recurrence of symptoms, and subsequent proctoscopic examination of four patients has given no evidence of chronic ulcerative colitis.

These patients have been observed only for from three weeks to eight months and for this reason our report is only a preliminary one. Because of the nature of the disease, it is likely that progress will not continue to be good in all these cases and we do not offer this treatment as a cure for chronic ulcerative colitis. We are inclined to believe that the drugs concerned are of value in the treatment of certain cases of chronic ulcerative colitis and that continued experience will enable a decision as to favorable types of cases for treatment. In a later paper, after further observation, we will publish a more detailed report.

In case 3 (table 3) improvement was just as striking as it was in the others for at least five months but thereafter there was some recurrence of symptoms, which have tended to persist in spite of further treatment with neoprontosil.

In case 7 the disease had been present for ten years with involvement of the entire colon. The patient had been bedfast for two months shortly before admission and had received considerable treatment without benefit. Following intensive treatment with neoprontosil, general improvement and lessening of the colonic symptoms resulted.

Case 8 must be regarded as the only failure in this group of cases. This patient was ill from stubborn chronic ulcerative colitis of long standing for which enterostomy had been suggested. His early response to di-methyl-di-sulfanilamide was

striking but did not persist. Peripheral neuritis necessitated immediate withdrawal of the drug. Subsequently enterostomy was performed and when he was dismissed from the clinic he had nearly recovered from the peripheral neuritis.

Table 4 represents three patients who had other disease besides chronic ulcerative colitis. In two of these, and possibly in all three, the other disease was such as to prevent the persistent improvement noted in the uncomplicated cases.

In case 10 (table 4) improvement was temporary. Marked diverticulosis of the sigmoid and descending colon possibly interfered with the treatment of the chronic ulcerative colitis.

In case 11 (table 4) chronic ulcerative colitis complicated biliary cirrhosis. The colitis responded favorably, although not completely, to the use of neoprontosil but the serious biliary cirrhosis prevented adequate treatment of the colitis.

In case 12 (table 4) improvement followed treatment with neoprontosil. However, because of exacerbation of symptoms and the presence of a mass in the right side of the abdomen, another roentgenogram of the colon was made. This disclosed the presence of a carcinoma of the colon as a complication of the ulcerative colitis. This finding was confirmed at operation.

TABLE 4.—Complicated Chronic Ulcerative Colitis Treated with Neoprontosil (Prontosil Soluble) or Similar Compounds

Case	Complication	Duration of Illness, Yr.	Result of Treatment	Period of Observation, Mo.	Drug Used	Toxic Reactions	Comment
10	Marked diverticulosis of colon	¼	Temporary improvement	2½	Neoprontosil	None	Symptoms recurred
11	Chronic biliary cirrhosis	½	Temporary improvement	8	Sulfanilamide Neoprontosil	Moderate None	Symptoms of colitis improved; inadequate treatment permitted
12	Multiple carcinomas of colon	5	Temporary improvement	3	Neoprontosil	None	Symptoms recurred and progressed

Only brief comment will be made concerning dosage, drug used and selection of patients suitable for treatment. Most of the patients received from 3.25 to 5 Gm. of sulfanilamide or neoprontosil daily for from ten days to two weeks. The same course was repeated several times, with intervals of a week or two between courses, and then the interval between treatments was gradually lengthened. At present we are modifying this plan somewhat by continuing administration of the drug in reduced dosage during what were previously the rest periods of the first few weeks of treatment.

As has been pointed out previously, neoprontosil possesses characteristics which make it the sulfonamide drug of choice in treatment of such conditions as chronic ulcerative colitis wherein prolonged therapy is indicated and severe toxic reactions may have serious consequences. Its lack of toxicity is evident in table 3.

Some of our associates at the Mayo Clinic have noted less favorable results than those we have had in cases of chronic ulcerative colitis in which treatment has been by means of the drugs under consideration. They have called attention to the occurrence of fatal jaundice in two such cases in which sulfanilamide was administered. In one case it is doubtful whether the sulfanilamide played an important role in the fatal result. The patient was very ill with fever, marked leukocytosis

and severe secondary anemia. In five days only 50 cc. of 5 per cent solution of neoprontosil and 140 grains (9 Gm.) of sulfanilamide were administered; jaundice was not noted until ten days after administration of the drugs had been discontinued. In the other case, however, it is probable that sulfanilamide was responsible for the fatal jaundice although it is reasonable to assume that the liver of this acutely ill patient had been damaged previously and that this injury made her particularly susceptible to the toxic action of sulfanilamide.

Such catastrophes demonstrate the necessity of care in selection of patients for treatment and in selection of the drug to be used. A patient who is not too ill and whose disease is of relatively mild degree offers the best prospect of improvement and presents a good margin of safety should a toxic reaction occur. Most of the patients in our series of cases have been carefully selected and are of this type.

Apparently sulfanilamide, neoprontosil and di-methyl-di-sulfanilamide are of value for treatment in selected cases of chronic ulcerative colitis. Di-methyl-di-sulfanilamide, however, should not be used at present because of the danger of peripheral neuritis which its use entails. Neoprontosil usually is preferred to sulfanilamide because it is better tolerated by the patient who has chronic ulcerative colitis and because it seems to be adequately effective.

SUMMARY

We have mentioned the use of sulfanilamide, di-methyl-di-sulfanilamide and neoprontosil by oral administration in the treatment of various infections. Sulfanilamide, although apparently possessing therapeutic advantages over the latter two preparations, nevertheless appears to have more of a tendency to produce toxic manifestations. Di-methyl-di-sulfanilamide, because of a tendency to produce peripheral neuritis, is contraindicated for general use at this time. Neoprontosil administered orally, while apparently less effective therapeutically than sulfanilamide, seems to be less likely to produce toxic manifestations and therefore is of value in some instances wherein sulfanilamide cannot be satisfactorily given. Certain cases of chronic ulcerative colitis seem to offer a favorable field for the use of neoprontosil or the cautious administration of sulfanilamide.

ABSTRACT OF DISCUSSION

DR. DWIGHT L. WILBUR, San Francisco: Sulfanilamide and its related compounds apparently possess greater value as chemotherapeutic agents than any other group of drugs developed since the synthesis of the arsenicals of the arsphenamine group. To some degree it is unfortunate that the almost universal use of the drug in the treatment of infections has occurred prior to the development of more adequate knowledge of the pharmacologic effects of this group of drugs. Because of this lack of knowledge, positive answers cannot be given to such important questions as the dosage of sulfanilamide which is adequate, as to the values for sulfanilamide in the blood which must be reached to insure a maximum therapeutic response, as to the interval of time over which the drug must be given, and as to the toxic effects of the drug and their prevention. The results which Dr. Bannick and his associates have presented are of great interest. They substantiate previously made reports of success of sulfanilamide in the treatment of a variety of infections and they add reports of the possible therapeutic value of sulfanilamide in chronic ulcerative colitis. It will be interesting to see whether the latter results can be duplicated by others and if they will persist for longer than a few months after treatment with sulfanilamide has been discontinued. It is important that

in the treatment of acute infections with sulfanilamide good results are obtained within a few days if the dosage is adequate. If the drug is administered in large doses and there is no effect on the acute infection within a few days, it is quite likely that the drug will be ineffective and it should be discontinued. Any one who has used sulfanilamide in more than a few cases is aware of some of the toxic manifestations which not uncommonly result and which lead to nausea, vomiting, vertigo, cyanosis, headache and nervous symptoms. Because these toxic manifestations are relatively common it is essential that every patient who receives the drug be under the daily observation of his physician. Two of the undesirable effects of the drug may be very simply controlled. By the simultaneous administration of sodium bicarbonate in relatively small doses one may overcome the acidosis which constantly accompanies administration of sulfanilamide. Cyanosis, which is due to the formation of methemoglobin, may be controlled by the administration intravenously to adults of 50 cc. of 1 per cent methylene blue.

DR. EDWIN E. OSGOOD, Portland, Ore.: Such studies are often hard to evaluate because of the difficulty of securing adequate controls. I have no clinical experience with these preparations but have used the method of marrow culture to make a comparative study of the same drugs. Marrow cultures infected with beta hemolytic streptococci were mixed thoroughly in one vial and subdivided into a series of vials, one of which was left as a control, and to the others concentrations of prontosil soluble (the disodium salt of 4-sulfamido-phenyl-2'-azo-7'-acetyl-amino-1'-hydroxynaphthalene-3',6' disulfonic acid), 1:10,000 sulfanilamide and other sulfanilamide derivatives were added. The concentrations of the more complex compounds were so calculated that the amount of sulfanilamide which could theoretically be derived from each was the same, namely 1:10,000. Pour plate colony counts were made at intervals. In these experiments sulfanilamide itself proved superior to the other preparations studied in the concentrations employed, but all the preparations were definitely of value, while they have practically no effect in ordinary bacteriologic medium. These experiments would seem to suggest that the effectiveness of the more complex compounds could be explained by the sulfanilamide liberated from them. It is my impression that the belief that prontosil soluble might be more effective than sulfanilamide has been based on the assumption that a concentration of 1:10,000 sulfanilamide was essential for effective action and the observation that doses of prontosil soluble which could not possibly give rise to that concentration of sulfanilamide were effective. In our marrow cultures, however, 1:100,000 sulfanilamide was sufficient for sterilization to occur in the majority of the cultures inoculated with small numbers of streptococci. The authors have arrived at the same plan of sulfanilamide therapy that our marrow culture studies showed to be desirable, namely that administration be begun promptly, that it be given at frequent intervals, preferably every four hours, day and night, and that the drug administration be continued until the cultures are negative even though the clinical symptoms have disappeared. If the authors' studies lead to a method of value in ulcerative colitis it is a very important contribution because this disease is difficult to control. Even though prontosil soluble is less effective in our marrow cultures than corresponding doses of sulfanilamide, it does not necessarily follow that it has no place in therapy since it may be of value given by mouth in the occasional patient who finds sulfanilamide too irritating to the stomach.

DR. RUSSELL L. HADEN, Cleveland: Dr. E. N. Collins of the Cleveland Clinic has used sulfanilamide in the treatment of eleven cases of chronic ulcerative colitis during the past year. The results have been excellent in eight cases. The drug has been administered by mouth and by retention enema.

DR. E. G. BANNICK, Seattle: I want to call attention to the importance of clinical observations in determining the true value of any new drugs such as these. It is not possible to determine accurately what the clinical results are going to be from the standpoint either of therapeutic effectiveness or of toxicity by experimental methods alone. This fact is clearly shown in the use of disulfanilamide. This drug has been

carefully studied by animal experimentation, in which it was shown to be much less toxic than sulfanilamide; and yet it was not until it had been tried clinically that the occurrence of peripheral neuritis was noted following the administration of the drug in some patients. I want again to emphasize the importance of proper selection of patients for the use of these drugs in the treatment of ulcerative colitis. I believe these drugs are of real value in the treatment of some patients afflicted with this disease, but it must be cautiously administered.

VITAMIN A DEFICIENCY AND DARK ADAPTATION

BERTHA L. ISAACS, M.B.

FREDERIC T. JUNG, Ph.D., M.D.

AND

A. C. IVY, Ph.D., M.D.

CHICAGO

Night blindness or hemeralopia as the result of qualitatively inadequate dietaries has been recognized from the time of Hippocrates.¹ However, for many years this condition was considered of rare occurrence except in certain communities or during periods of fasting, famine or war.

The recent reports by Jeans and his co-workers,² Jeghers,³ Park,⁴ Corlette and his associates,⁵ Barborka⁶ and others suggest that this condition is relatively frequent. The literature is in agreement as to the infrequency of frank cases of night blindness associated with xerophthalmia, xerosis and keratomalacia in the United States. Each of these workers was tested for impaired dark adaptation by means of an instrument designed for clinical use and known as the biophotometer. This instrument purports to determine vitamin A deficiency by measurement of the degree of impairment of the light threshold and the rate and degree of dark adaptation. Other means for testing dark adaptation have been utilized in the past. Among these are the glowing platinum wire,⁷ the Tscherning glasses,⁸ and the Edmund test letters.⁹ Since the introduction of the Birch-Hirschfeld¹⁰ photometer several others have been recommended.¹¹

It is not in the scope of the present paper to review all the scientific literature pertaining to dark adaptation

and its measurement, or the relationship between vitamin A deficiency and abnormalities of vision. Those interested may consult the articles by Adams,¹² Hecht,¹³ Wald,¹⁴ Fridericia and Holm,¹⁵ Holm¹⁶ and Tansley.¹⁷

Thus far only six groups of workers¹⁸ have reported the results of their studies pertaining to the relation of vitamin A to dark adaptation as measured by the biophotometer, although it is well known that many are working with this instrument. Only one of the clinical reports, that of Palmer and Blumberg,¹⁸ has criticized the use of the biophotometer as a test for vitamin deficiency. In making a second such report we do so not in a spirit of destructive criticism but in an effort to clarify certain problems that became manifest to us while we were using the apparatus.

PROCEDURE

Our first group studied was composed of twenty apparently healthy graduate students between the ages of 21 and 45. Daily readings were made with the biophotometer. The readings were obtained on each person at the same hour for ten consecutive days. We followed the technic prescribed by Jeans, Blanchard and Zentmire² with two exceptions: One was that each day before entering the dark room the subject sat for five minutes in a room with a known constant illumination. The other exception was that we repeated the three minute light exposure. This provided us with a series of readings as follows:

1. Immediately after entering the dark room.
2. Five minutes after entering the dark room.
3. Ten minutes after entering the dark room.
- Light for three minutes.
4. Thirty seconds after light.
5. Three minutes after light.
6. Six minutes after light.
7. Ten minutes after light.
- Light for three minutes.
8. Thirty seconds after light.
9. Three minutes after light.

The second group of persons whom we studied consisted of 123 sophomore medical students between the ages of 19 and 34 years. The same routine was followed and two sets of readings were made on each student. The second set was obtained one week after the first at the same hour of day. All our data were then subjected to statistical analysis. This was done because we felt that the objection to most of the work published in connection with the biophotometer is that conclusions have been drawn not from numerical treatment of readings but from purely intuitive interpretation of curves. The standards used have been obtained by dividing large groups of subjects into low,

midzone and high according to their readings, and the important logical step of substituting the word "subnormal" for the word "low" has not been subjected to critical analysis. We felt it necessary to determine whether any given subject would give constant readings on the machine and whether the machine was sufficiently reliable to permit detection of day to day variations in given subjects, and significant differences among differ-

curve whose equation we were able to obtain in the case of our own instrument. This is:

$$(b-x)$$

$$\text{or } \log y = (b-x) \log a$$

y = brightness of test light in millifoot candles
 x = dial reading
 a = constant = 1.096
 b = constant = 69.47

The properties of this equation are such that when a series of human subjects are rated according to their biophotometer performance, in terms of millifoot candles, the supernormal and normal readings are crowded together into a very narrow zone while the subnormals appear conspicuously isolated. In an effort to obviate this some investigators have plotted their results on semilogarithmic paper. This does obviate the crowding of normal and supernormal readings. However, one could avoid the two successive steps by simply working with the dial readings that one started with. Table 2 shows that index B yields a symmetrical distribution in which the supernormal, normal and so-called subnormal readings are all visible. It should be noted that if this were a set of measurements on height, weight or other dimensions the persons in

Self correlation of twenty-five pairs of values of B = 0.805.

ent subjects. Our first step was to calculate the probable error of each one of the nine readings obtained on the ten consecutive days for the twenty graduate students. We also determined the self correlation of pairs of readings from the entire 143 subjects studied; this statistical device is described by Sorenson.¹⁹

DATA AND COMMENT

The first fallacy encountered arose from the fact that three of the most conspicuous points on the curve obtained by plotting the readings on the photometer were the most unreliable. These points are given by readings 1, 4 and 7 (table 1). Unless the data are studied in this manner one is easily deceived as to the reliability of the readings obtained. The narrow range in which a given reading must fall creates a false impression of constancy; the method of self correlation reveals how meaningless this constancy is. Table 1 also shows that the most reliable reading is not 4 (on

which most observers place reliance) but readings 2, 3, 6 and possibly 5. From these four we obtained by simple addition a value which we called index B. It gives a self correlation of 0.805, which is high enough to be passable.

The second fallacy is involved in the translation of dial readings into millifoot candles. This is done by means of a table supplied by the manufacturers. Graphing the figures in the table gives an exponential

the lower percentiles would not necessarily be called subnormal. In short, it is necessary to recognize the possibility that constitutional factors may be responsible for some of the individual differences.

A third fallacy assumes a particularly striking form as a result of the conspicuous position given to the so-called subnormal readings when the measurements are stated in terms of millifoot candles. According to some observers when their "subnormal subjects" are given halibut liver oil or vitamin A in any other form they promptly show a striking improvement. Table 3 shows that they must by all the laws of probability show an equally striking improvement if left untreated. This phenomenon is reported in more detail in a recent article by Jung.²⁰ This fallacy arises whenever subnormal subjects are selected from a large group by a test which is strongly affected by chance errors, as we have shown reading 4 to be. The fallacy can be avoided by subdividing the subnormal subjects into two groups, one part of the group being used as controls, as we have done in a series now being studied. This has been neglected in two published articles.²¹ We have proposed for this fallacy the term "centripetal

21. Jeghers, J. A. Corlette, Youmans, Frank and Corlette.

drift" because it affects the upper as well as the lower percentiles in any distribution; it is a simple consequence of the laws of probability. If biophotometer readings are translated into millifoot candles the supernormal readings are so crowded against the normal, to begin with, that the effect on the supernormal readings escapes observation.

N = 113; r = 0.02 (correction coefficient).

Finally we reach the original purpose of our study, which was the correlation of dietary intake of vitamin A with the dial readings to determine whether such a correlation is significant. The medical students studied were asked to fill out carefully formulated questionnaires on which they listed in detail their total food intake for five days. From these reports we calculated their intake of vitamin A as international units per day, using the tables compiled by Eddy and Dalldorf.²² Lowest values were selected for each food; therefore, the total represents the minimal rather than the most probable intake. When the daily intake was plotted against index C (latter obtained by averaging index B obtained on first two readings by photometer) it became evident at once that the correlation was near zero (table 4). For the 113 subjects who submitted complete reports the correlation coefficients proved, in fact, to be +0.02. It seemed possible that the five day period might not represent the habitual gastronomic life of the students; hence we asked each one to list separately an estimate of the usual weekly intake of those foods known to be richest in vitamin A. Plotting the results against index C we again found an insignificant correlation, i. e., +0.06 for 116 subjects (table 5). The results at first led us²³ to conclude that in the subjects we had studied there was no correlation between dietary vitamin A and dark adaptation and that the chief difficulty in the way of revealing such a correlation, if it did exist, was the inaccuracy of the dietary calculations. We are now forced to conclude that this is not entirely true but that the chief difficulty was in the method we used for measuring dark adaptation.

It should be noted that the daily intake of vitamin A for the entire group ranged from at least 1,650 to 9,725 international units. The report of Jeghers on a similar study indicated that the mode for his sub-

normal and normal subjects combined was from 3,001 to 4,000 international units; for ours it was approximately the same. This indicates that our subjects were obtaining, as were those of Jeghers, a better than "physiologic minimum" of vitamin A in the diet.²⁴

In addition to the dietary information obtained from the questionnaires, each student was asked to answer specific questions as to the following:

1. Ability to see at night.
2. Ability to drive an automobile at night.
3. The time required for him to see in a darkened theater.
4. Presence of lacrimation.
5. Dryness of eyeballs.
6. Burning of eyes.
7. Dryness, itching or scaling of the skin.
8. Presence of any skin lesions.
9. Dryness and falling of the hair.
10. Occurrence of headaches.
11. Weakness or excess fatigue.
12. Loss of weight.
13. Frequency of colds.
14. Presence of constipation.
15. Use of laxatives.
16. Appetite, dyspepsia and the like.
17. Chronic disease (sinusitis, bronchitis and the like).

Tabulation of the answers to the preceding questions revealed nothing significant in relation to the amount of vitamin A ingested or to the biophotometer readings. In fact, many whose vitamin intake was at a high level recorded the presence of some of the symptoms generally considered indicative of vitamin A deficiency. The reverse was likewise true. Calculation of "biserial r" by the method described by Sorenson¹⁹ confirmed the impression gained by simple inspection of the tabulated data. In spite of the fact that our

subjects were normal young adults and that much of the questionnaire was of a subjective nature, we believe that any trends toward correlation could have been easily detected.

SUMMARY

Our original purpose in this study was to determine whether a correlation exists between dietary intake of vitamin A, biophotometer readings and clinical symptoms. If such a correlation exists it would be possible

22. Eddy, W. H., and Dalldorf, Gilbert: The Avitaminoses, Baltimore, Williams & Wilkins Company, 1937, p. 316-321.

to utilize this photometer clinically for the detection of deficiency of vitamin A. Very early we found that it was necessary to know more than we did about the performance of the apparatus before the data obtained could be wisely interpreted. This led us into an analysis which indicated a number of fallacies, the significance of which is readily apparent.

CONCLUSIONS

1. The intake of vitamin A of 143 healthy medical students as determined by calculation from their diets ranged from at least 1,650 to 9,725 international units per day.

2. No correlation could be detected between dietary vitamin A and biophotometer readings. Neither could a correlation be noted in our subjects between vitamin A intake and clinical signs and symptoms of A deficiency.

3. We believe that nothing is gained by translating dial readings of the biophotometer into millifoot candles, because errors are introduced and the effects of certain fallacies are exaggerated thereby.

4. We also believe that the criteria generally chosen for the recognition of vitamin A deficiency by means of the biophotometer are not the most reliable criteria.

5. Far more study is essential before the biophotometer or any similar instrument can be used per se for the detection of vitamin A deficiency in the human being.

DURATION OF SMALLPOX IMMUNITY

DAVID T. LOY, M.D.

AND

M. W. HUSBAND, M.D.

MANHATTAN, KAN.

In 1936 a study was made¹ of smallpox immunity in 1,053 matriculating college students at Kansas State College. A similar study of 986 students made in September 1937 with additional data on the duration of smallpox immunity and the effect of multiple vaccinations constitutes the basis of this report. Table 1 gives in tabulated form the detailed histories and results on the vaccinated group. This college age group was very largely derived from rural areas and small towns in Kansas.

Of the vaccinated group 74.9 per cent gave a positive history of previous vaccination against smallpox and had a visible scar; 3.3 per cent had not had a previous vaccination but gave a positive history of smallpox; 20.4 per cent had neither been vaccinated nor had smallpox but gave a positive history of chickenpox; 1.2 per cent gave an entirely negative history for previous vaccination against smallpox, smallpox and chickenpox.

The multiple puncture method of vaccination was employed on the skin over the insertion of the deltoid muscle. No dressings or protective shields were used and no secondary infections were encountered. No instance of generalized vaccinia occurred in the group vaccinated. Each student was examined on the second, fourth and seventh days and later if indicated after the date of vaccination. The results were recorded accord-

ing to the following classification: (a) Immune or immediate reaction: the development of a small area of redness with or without the presence of a papule, the height of the reaction being reached within twenty-four to forty-eight hours after vaccination. (b) Primary take: the formation of a papule, vesicle and pustule, the height of the reaction being reached within six to ten days after vaccination. (c) Secondary take: same as primary take except that it occurred in an individual with a visible vaccination scar or with pockmarks. (d) Accelerated reaction: same as primary take except that the reaction was less pronounced, developed more rapidly and disappeared in a much shorter period of time.

Of the vaccinated group 35.3 per cent had immune or immediate reactions, 39.8 per cent had accelerated

Chickenpox is recorded only in those cases in which there was a negative history of previous vaccination and smallpox.

reactions, 22.7 per cent had primary takes and 2 per cent had secondary takes. The results of the vaccinations of this group are in general similar to those obtained in the group vaccinated in 1936 (table 2). It may be noted that there are more primary takes recorded than there are students with an entirely negative history or with a history of chickenpox only. This result may be partly accounted for by Leake's² observation that smallpox does not immunize against vaccination quite as well as against itself. Thus, an individual who has had smallpox may have a primary take when vaccinated against smallpox.

Of the group vaccinated 64.5 per cent (primary takes, secondary takes and accelerated reactions) were in some degree susceptible to smallpox. Of the group previously studied (1936) 61.5 per cent were susceptible to smallpox in some degree. Of the students 74.9 per cent had previous vaccinations. In the former group 78.1 per cent had previous vaccinations.

From the Student Health Service, Kansas State College.
The smallpox vaccine used in this study was generously supplied to us by the Kansas State Board of Health.

2. Leake, J. P.: Questions and Answers on Smallpox and Vaccination, Pub. Health Rep. 42:221 (Jan. 28) 1927.

Histories of the dates of previous smallpox vaccinations apparently were accurately obtained from 720 students. Table 3 shows the duration of smallpox immunity in 661 members of this group who had had only one previous vaccination against smallpox. There is considerable variation in the individual cases, but

TABLE 2.—Comparison of 1936 and 1937 Groups

Year	Number Vaccinated	Per Cent with Previous Vaccination	Per Cent Susceptible to Smallpox
1936.....	1,053	78.1	61.5
1937.....	986	74.9	63.7

the average of the group shows about 20 per cent more students with complete immunity in the group vaccinated from one to five years previously than in the group vaccinated from six to ten years previously. After ten years the number with complete immunity does not decrease appreciably. It may be noted that in the one to five year group there is 1.5 per cent total loss of immunity (secondary takes) while in the six to ten year group there is 4 per cent total loss of immunity. The number of persons with complete immunity at similar periods after previous vaccination in this group is considerably lower than that given by Dearing and Rosenau,³ who in their study of duration of smallpox immunity following vaccination show that 95 per cent of those vaccinated ten years or less after their vaccination had complete immunity and that of those vaccinated from ten to nineteen years after their first vaccination 67 per cent had complete immunity. The reason for this difference is not obvious but may be the difference in density of population of the areas from which the two groups were derived.

Of the 986 students in the vaccinated group only fifty-nine, or 5.9 per cent, had been vaccinated more than once previously. Only one of this group with

multiple previous vaccinations had been vaccinated more than twice. Table 4 gives a summary of the results of the vaccination against smallpox in this group and compares the duration of smallpox immunity in the single and multiple previously vaccinated groups. Of the group with multiple previous vaccinations within one to five years 78.8 per cent had complete immunity

and there were no cases of secondary takes, whereas in the group with single previous vaccinations within one to five years there were 56.8 per cent with complete immunity and 1.5 per cent with secondary takes or total loss of smallpox immunity.

The results of this group of smallpox vaccinations show that there is a wide individual variation in the duration of smallpox immunity following vaccination, that the number of persons with complete immunity from one to five years after previous vaccination is greater in the group with multiple previous vaccinations than in the group with single previous vaccinations and that in general there would be an increase in the number of completely immune persons if each person was revaccinated once in every five years. These results agree generally with the opinion of Leake,² who states that the immunity to smallpox afforded by vaccination is lost by different persons at different rates and that each individual should be vaccinated ordinarily once in every five to ten years.

As in 1936, there were only a few students who refused vaccination. Woodward and Feemster⁴ have shown definitely that the number of smallpox cases per unit of population is lower in those states with compulsory vaccination than in those states without com-

TABLE 4.—Comparison of Multiple and Single Vaccinations

Number of Previous Vaccinations	Number of Years Since Last Vaccination	Number Vaccinated	Results		
			Immune Reactions	Accelerated Reactions	Secondary Takes
2	1 to 5	52	41 (78.8%)	11 (21.1%)	0

2	6 to 10	6	3	3	0

pulsory vaccination. In Massachusetts, where there is a compulsory smallpox vaccination law, there has been no case of smallpox reported to the state board of health during the past five years.⁵ Since there is no provision for the ideal preventive procedure (compulsory vaccination) in the state of Kansas, we feel that a program of making smallpox vaccination available in an acceptable manner should meet with a favorable response from the inhabitants of the state and aid in the reduction of cases of smallpox.

SUMMARY

1. Of the students who matriculate at Kansas State College (a) approximately one fourth have never been vaccinated against smallpox, and (b) approximately two thirds are in some degree susceptible to smallpox.

2. Only 5.9 per cent of the 1937 group had been vaccinated more than once previously.

3. There are about 20 per cent more persons with complete immunity in the previously vaccinated one to five year group than in the group vaccinated from six to ten years previously.

4. There are about 20 per cent more persons with complete immunity in the multiple previously vaccinated group than in the once previously vaccinated group.

5. The method of noncompulsory vaccination used has proved to be almost 100 per cent acceptable to the student group.

Clinical Notes, Suggestions and New Instruments

A SHOULDER ABDUCTION CAP

L. E. PAPURT, M.D., CLEVELAND

The present methods of maintaining abduction of the shoulder in the ambulatory patient consist of abduction and airplane splints or plaster casts. The splints are very cumbersome and uncomfortable and require constant attention and adjustment. Plaster casts prevent the administration of physical therapy and active use, which are essential in many shoulder conditions. In fractures about the shoulder, where complete immobilization is desired, splints or casts are essential. However, there are many conditions in which abduction is the only indication. In these cases I have found the abduction cap here illustrated very efficient, allowing patients to be freely ambulatory and often attending to their business.

Application of shoulder-abduction cap.

As is noted in the accompanying illustration, the shoulder abduction cap consists merely of a canvas aviator-type cap and a padded leather wristlet. The cap buckles under the chin and should fit snugly. There is a reinforced loop on top of the cap through which the strap of the wristlet is threaded before it is buckled. At first I used the heavy leather cap worn by aviators but I have found that the ordinary canvas cap worn by boys in winter serves just as well and is not as heavy or as expensive.

I have used this cap with great satisfaction both to myself and to the patient in the following conditions:

1. Subdeltoid bursitis. In both traumatic and infectious bursitis, abduction of the shoulder is an essential part of the treatment. It has been especially useful in elderly persons who fall on the outstretched hand, sustaining both a Colles fracture and a subdeltoid bursitis. After the fracture has been reduced and a cast applied to the wrist, the arm is kept in abduction by the cap, and massage to the shoulder for a few days avoids

the stiff shoulder that is seen so often in an elderly person who sustains a Colles fracture and carries the arm in a sling.

2. Following manipulations for subdeltoid bursitis and "frozen shoulders."

3. Rupture of the supraspinatus tendon. As a postoperative form of fixation and abduction the cap has been ideal. In incomplete ruptures in which operative intervention is not necessary it also serves well. I have not had occasion to try it on infants following tenotomy of the sternomastoid muscle or tenotomies in birth palsy deformities, but I am sure that it could readily be used in these conditions. There will probably be other shoulder conditions in which the cap may be used with satisfaction both to the physician and to the patient.

CONCURRENT TIC DOULOUREUX AND MÈNIÈRE'S DISEASE TREATED SURGICALLY

H. MASON SMITH, M.D., AND MILLARD WHITE, M.D.
TAMPA, FLA.

Since no report of a case has been found in which tic douloureux and Ménière's disease occurred synchronously and were relieved simultaneously in one operation, the case here presented is believed to be unique in medical literature. The patient experienced complete relief of both syndromes after the operation.

REPORT OF CASE

Mrs. G. H., a white woman aged 43, was admitted to the Tampa Municipal Hospital Dec. 14, 1937, complaining chiefly of vertigo and of tinnitus and deafness in the left ear.

About six years previously the patient had begun to have pain and tenderness over the left frontal part of the scalp and, a few months later, a dull aching pain in the left upper part of the face. Much dental work brought no relief, and the pain became progressively worse until it finally assumed the character typical of the tic douloureux, with shooting pains to the midline of the face and trigger zones. From time to time injections of alcohol were given peripherally; the last one, in October 1937, resulted in relief of the pain, which lasted until admission.

Three weeks before she entered the hospital, the patient stumbled on some steps and fell. She was unconscious for a few minutes, but no injury to her head was observed. For a number of weeks before this injury occurred she had had a ringing in her left ear, headache and some ataxia, characterized by "running into things." Two weeks before admission vertigo developed, with nausea and vomiting, severe headache on the left side and diplopia. She was unable to raise her head from the pillow without dizziness and nausea; her head would fall to the left; objects would rotate. Any sudden motion before her eyes or the turning of her eyes to the left produced vertigo and nausea. A spinal puncture one week before admission resulted in relief of the diplopia and diminution in the severity of the headache, but the other symptoms remained the same and the headache returned to its original intensity. For a month or more prior to admission the patient had suffered from general weakness, polydipsia, sensitiveness to cold and nervousness.

No member of the patient's family had ever had Ménière's disease or tic douloureux, and the family history was otherwise irrelevant. The past medical history showed that at the age of 11 the patient had received a head injury in the left occipital region from a blow. At that time she remained unconscious for twelve hours or more and complete paralysis of all extremities developed, the left side clearing more rapidly than the right. She was confined to her bed for almost a year as a result of this injury. At the age of 22 she married and shortly thereafter was subjected to a suspension of the uterus. Of six pregnancies, two resulted in miscarriages. Twelve years before admission some perineal work was done, and the tubes and ovaries were removed. Two years afterward a complete hysterectomy was performed, and six months later there developed on the left side a perinephric abscess, which was treated by incision and drainage.

The physical examination showed a considerable degree of tenderness of the left frontoparietal part of the scalp. There

was some paresis, with diminished sensibility over the left side of the face, but no muscular atrophy was noted. The pupils of the eyes were equal, reacting to light and in accommodation, but were slightly irregular in contour. There was no disturbance of motility, nor was nystagmus or exophthalmos present. The disks were normal, and the corneal reflex was intact. There was no tremor of the tongue, and it protruded in the midline. The upper teeth had been removed. In both ears the drum and canal were normal. Weber's sign was not present. The left ear showed a nerve deafness approximating 25 per cent. All tendon reflexes were equal but hyperactive. The abdominal reflexes were present and equal. There was no atrophy, and no pathologic reflexes were present. The finger-nose and knee-heel tests were done well. There was no adiadokokinesis. Romberg's sign was slightly positive, with an inclination of the body to fall to the right. Examination of the blood and spinal fluid gave negative results. The basal metabolic rate was minus 27 per cent.

A diagnosis of tic douloureux and Ménière's disease was made and was confirmed by Dr. Walter E. Dandy of Baltimore, to whom the patient was referred. Jan. 11, 1938, Dr. Dandy totally divided the left sensory root and partially divided the eighth

The operation.

nerve. The operation was followed by immediate relief of all symptoms, and they have not returned. The patient is now at home in complete comfort.

The accompanying drawing of the operation done by Dr. Dandy shows the proximity of the nerves involved and makes obvious the ease with which they may be divided in the same operation.

1019 Citizens Bank Building.

Scientific Discoveries of Claude Bernard.—It is now more than half a century since Bernard died and sufficient time has elapsed to permit an estimate of the value of his work. Physiologists are all agreed that in four different departments of their science the name of Claude Bernard stands at the head of the list of those who have made lasting contributions. These discoveries all belong to the first, or Collège de France, period and they are (1) the functions of the pancreas in digestion, (2) the glycogenic function of the liver, (3) the vasomotor system, (4) the action of certain poisons, notably curare and carbon monoxide. None of these discoveries came as a result of his earliest investigation, but, with the exception of the action of poisons, they were a natural sequel to his initial experimental work.—Olmsted, J. M. D.: *Claude Bernard, Physiologist*, New York, Harper & Bros., 1938.

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

PACIFIC AIRVENT NOT ACCEPTABLE

Manufacturer: Pacific Manufacturing Corporation, 4223 Lake Street, Chicago.

The Pacific Airvent is an air filter designed to provide relief for sufferers from hay fever and asthma by removing a high percentage of the pollen, dust and dirt from the air in a given room. For efficient service, according to the firm, the unit will accommodate a room with air capacity of 8,000 cubic feet; this may be approximately 20 by 40 feet in dimensions. The unit proper is a cabinet which slips into a heavy gage metal base with felt bottom which may be fastened to almost any window sill. The exterior of the cabinet is finished in metal to prevent rusting while the inside is of seasoned wood. It is 24 inches wide by 18 inches deep by 12 inches in height and weighs approximately 60 pounds.

In order to make the apparatus useful for ventilation in winter as well as summer, it has been equipped with rubber insulation or weather-stripping. No-draft stoppers are placed between the top of the sash of the lower window and the pane of the upper window to prevent outside air from entering here when the unit is installed. Burglar latches are placed between the upper sash and top edge of the lower sash at either side of the window to prevent prowlers from raising the window higher.

In operation a damper lever, located under the top door of the cabinet, controls the amount of outside air admitted. This volume control regulates input at two speeds, high and low. The air is drawn into the unit over the top of the filter and through the fan blower housings. These consist of two Sirocco fans, placed one at either side of the motor. Their housings are insulated for acoustical purposes. The filtered and cleansed air enters the room through louvers in the grill work in the cabinet front which direct it up, down or straight ahead.

Wilson "spider-web" filters are supplied with the unit. The firm claims that these filters remove 97.47 per cent of the pollen from the air and 98 per cent of the dust, dirt and soot.

Electrical details are as follows: Reynolds motors are installed where units are to be used with alternating current. General Electric or Bodine motors are installed where direct current is required. On high speed the unit consumes less than 60 watts per hour. On low speed the unit consumes approximately 30 watts per hour. Alternating or direct current motors are optional. With pilot tube sets the Airvent produces over 300 C. F. M.'s. These tests were made by use of air ducts divided evenly at the ends into small spaces. Tests were made in each space and averages taken from these tests.

Another Pacific Airvent feature, according to the firm, is the recirculation filter, which cleans the room air itself. This is done by closing the outside damper entirely and then lifting the door on top of the cabinet approximately two inches. The room air is then taken into the unit, filtered, cleaned and recirculated. Whether outside or inside air is used, it is said to be propelled gently to every part of the room, thereby eliminating drafts.

In order to substantiate the claims made for the filter, tests were made by an investigator acceptable to the Council. Although the unit appeared to be well constructed, the filtering effectiveness claimed by the manufacturer was not substantiated by the Council investigator. The filter is composed of a very loose network of coarse hairs impregnated with oil. Although there are evident microscopic openings in the filter, the manufacturer seems to expect that the devious paths through the hair and oil will trap most of the pollen. The investigator was not able to duplicate the firm's figures for percentage of pollen removed. In the Council's tests an average of 88 per cent of ragweed pollen was removed by the filter. This removal of pollen, in the opinion of the Council, is insufficient to alleviate hay fever symptoms.

The advertising matter submitted with the unit contained certain unsubstantiated claims such as the statements that the unit will save fuel and freshen air contaminated by cooking odors.

In view of the foregoing report, the Council on Physical Therapy voted not to include the Pacific Airvent filter in its list of accepted devices because the filtering mechanism is not efficient for removal of pollen and the advertising matter contains certain unsubstantiated statements.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

ESTRONE (THEELIN).— $C_{18}H_{22}O_2$ —3-hydroxy 17-keto Δ 1,3,5—estratriene. A crystalline estrogenic steroid obtained from the urine of pregnancy. The estrogenic activity of 0.1 microgram (1 ten millionth of a gram) of a standard preparation of estrone constitutes 1 international unit. The terms

Estrone and Theelin are nonproprietary synonyms.

Actions and Uses.—Estrone (theelin) is used in the treatment of symptoms of the menopause, natural or artificial, of certain other conditions related to deficiency of estrogen, and of gonorrheal vaginitis in children. See general article Ovary, New and Nonofficial Remedies, 1938, p. 333.

Dosage.—In disturbances of the menopause 0.02 mg. (200 international units) to 1.0 mg. (10,000

international units) intramuscularly one or more times a week. The smaller doses may be administered in aqueous solution, the larger in oil. Estrone may also be administered in vaginal suppositories. Beginning doses should be small to test the response of the patient and the dosage must be adjusted to the response.

For gonorrheal vaginitis in children from 0.02 to 0.2 mg. (200 to 2,000 international units) in glycerogelatin suppositories, daily or as required. This may be supplemented by intramuscular injection of small doses of the oil solution, if necessary. Changes in the secondary sex organs may be produced by this therapy, particularly if it is too prolonged. These changes usually regress on cessation of treatment.

Estrone is effective by mouth if the dosage is adequate.

Estrone occurs as a white, odorless, well defined, crystalline substance. During heating on the microscopic heating stage, characteristic rearrangement of the crystalline structure takes place at 220, 240 and 256 C. The substance melts sharply at 260 C. (± 2 degrees). Twenty mg. heated for five hours at 80 C. under vacuum of 2 mm. of mercury over phosphorus pentoxide gave no appreciable loss in weight. Practically insoluble in water; soluble in alcohol and in dioxane; also soluble in oils. Transfer approximately 0.01 Gm. of estrone accurately weighed to a 1 cc. microvolumetric flask; fill to the mark with freshly distilled dioxane and determine the optical rotation after the U. S. P. XI method, page 459, using a 2 dcm. microtube: the specific rotation $[\alpha]_D^{25}$ is +164.6 degrees (± 5 degrees).

Dissolve about 0.09 Gm. of estrone in a pyridine (6 cc.) and acetic anhydride (2 cc.) mixture (3:1) and heat at 95 C. under a micro reflux condenser for twenty-four hours. Transfer the solution to a 250 cc. flask containing 100 cc. of ice-cold water and titrate with 0.1 normal sodium hydroxide: the acetic acid value is not more than 43 nor less than 41, equivalent to one acetylated hydroxyl group. [A blank determination must be made for pyridine acetic acid and anhydride] (J. Biol. Chem. 91: 991, 1931).

Dissolve approximately 0.05 Gm. of estrone in a pyridine (6 cc.) and acetic anhydride (2 cc.) mixture (3:1) and heat at 95 C. under a micro reflux condenser for twenty-four hours. Let stand at 37 C. for another twenty-four hours. Add 10 cc. of 50 per cent alcohol and evaporate under vacuum to a thick syrup. Add very gradually about 50 per cent alcohol (1 cc.) and set aside for crystallization. Filter the crystals and recrystallize twice from 95 per cent alcohol. The melting point of the monoacetate of theelin is 126 C.

Dissolve 0.05 Gm. of estrone and 0.05 Gm. of hydroxylamine in 10 cc. of 95 per cent alcohol; acidify with 1 cc. of concentrated acetic acid and heat under reflux for five hours. Add 10 cc. of water and the precipitate thrice from 95 per cent alcohol. The melting point of the oxime is between 230 C. and 240 C. The micro Dumas nitrogen determination after the Pregl method gives a nitrogen content of not more than 5.2 per cent nor less than 4.6 per cent.

Transfer approximately 2 mg. of estrone, accurately weighed, to a previously weighed micro platinum boat, add 0.05 cc. of dilute sulfuric acid (1:5). Incinerate in the micro muffle oven: no residue should remain. Microcarbon and hydrogen analysis, according to Pregl's method, should give a carbon content of not more than 80.3 per cent nor less than 79.7 per cent, and a hydrogen content of not more than 8.5 per cent nor less than 7.9 per cent.

Estrone crystals exhibit a strong bluish-white fluorescence under filtered ultraviolet light.

The dosage forms of brands of estrone are biologically assayed, the assay being under control of the St. Louis University committee.

Theelin-P. D. & Co.—A brand of estrone (theelin)—N. N. R.

Manufactured by Parke, Davis & Company by license from St. Louis University under U. S. patents 1,967,350 and 1,967,351 (July 24, 1934; expire 1951). No U. S. trademark.

Ampules Theelin Aqueous, 1 cc.: Each cubic centimeter contains 0.02 mg. (200 i. u.) theelin in aqueous solution.

Ampules Theelin in Oil, 1 cc.: Each cubic centimeter contains 0.1 mg. (1,000 i. u.), 0.2 mg. (2,000 i. u.) or 1 mg. (10,000 i. u.) of theelin in a solution in peanut oil.

Vaginal Suppositories Theelin: Each suppository contains 0.2 mg. (2,000 i. u.) in a glycerogelatin base.

ESTRIOL (THEEOL).— $C_{18}H_{24}O_3$ —3,16,17-trihydroxy Δ 1,3,5—estratriene. A crystalline estrogenic steroid isolated from the urine of pregnancy. Estriol is much less actively estrogenic than estrone. The terms Estriol and Theeol are nonproprietary synonyms.

Actions and Uses.—Estriol (theeol) is used orally in the treatment of the menopause, natural or artificial, of certain other conditions related to deficiency of estrogen, and of gonorrheal vaginitis in children. See general article Ovary, New and Nonofficial Remedies, 1938, page 333.

Dosage.—Orally from 0.06 to 0.12 mg. from one to four times a day, alone or as supplement to parenteral therapy.

Estriol occurs as a white, odorless, micro crystalline powder. During heating on the microscopic heating stage, rearrangement of the crystal structure takes place at 270 C. and 275 C. The substance melts sharply at 282 C. (rate of heating, U. S. P. XI, 4 degrees in one minute—Kofler microscopic heating stage). Twenty mg. of estriol heated for five hours at 80 C. under vacuum of 2 mm. over phosphorus pentoxide gives no appreciable loss in weight. Practically insoluble in water; soluble in alcohol and dioxane; also soluble in oils. Transfer approximately 0.04 Gm. of estriol, accurately weighed, to a 1 cc. microvolumetric flask; fill to the mark with freshly distilled dioxane and determine the optical rotation after the U. S. P. XI method, page 459, using a 2 dcm. microtube. The specific rotation $[\alpha]_D^{25}$ is +58 degrees (± 5 degrees).

Dissolve approximately 0.06 Gm. of estriol, accurately weighed, in a pyridine (6 cc.) and acetic anhydride (2 cc.) mixture (3:1) and heat under a micro reflux condenser for twenty-four hours at 95 C. Transfer the solution to a 250 cc. flask containing 100 cc. of ice-cold water and titrate with 0.1 normal sodium hydroxide: the acetic acid value is not more than 129 nor less than 121, equivalent to three value is not more than 129 nor less than 121, equivalent to three acetylated hydroxyl groups. [A blank determination must be made for pyridine acetic acid and anhydride] (J. Biol. Chem. 91: 655, 1931).

Dissolve approximately 0.04 Gm. of theelin in a pyridine (6 cc.) and acetic anhydride (2 cc.) mixture (3:1) and heat under a micro reflux condenser for twenty-one hours at 95 C. Let stand at 37 C. for another twenty-four hours. Add 10 cc. of 50 per cent alcohol and evaporate under vacuum to a thick syrup. Add very gradually about 1 cc. of alcohol and set aside for crystallization. Filter the crystals and redissolve in 3 cc. of 95 per cent alcohol. Evaporate the alcohol and dissolve the residue in 4 cc. of pyridine. After addition of 16 cc. of water a white flocculent precipitate occurs; recrystallize twice from 90 per cent alcohol; dry the crystals in vacuum at 80 C. over phosphorus pentoxide: the melting point of the triacetate is 126 C. (± 1 degree).

Transfer approximately 2 mg. of estriol, accurately weighed, to a previously weighed micro platinum boat, add 0.05 cc. of sulfuric acid (1:5), incinerate in the muffle oven: no residue should remain. Micro carbon and hydrogen analysis, according to Pregl's method, gives a carbon content of not more than 75.2 per cent, nor less than 74.6 per cent, and a hydrogen content of not more than 8.7 per cent, nor less than 8.0 per cent.

Estriol crystals exhibit a reddish fluorescence under filtered ultraviolet light.

The dosage forms of brands of estriol are biologically assayed, the assay being under control of the St. Louis University committee.

Theeol-P. D. & Co.—A brand of estriol (theeol)—N. N. R.

Manufactured by Parke, Davis & Company by license from St. Louis University under U. S. patents 1,967,350 and 1,967,351 (July 24, 1934; expire 1951). No U. S. trademark.

Kapsels Theeol, 0.06 mg.: Each kapsel (sealed gelatin capsule) contains 0.06 mg. theeol.

Kapsels Theeol, 0.12 mg.: Each kapsel (sealed gelatin capsule) contains 0.12 mg. theeol.

SULFANILAMIDE (See New and Nonofficial Remedies, 1938, p. 450).

Sulfanilamide Tablets, 5 grains.
Prepared by Charles C. Haskell & Company, Inc., Richmond, Va. No U. S. patent or trademark.

MEDICAL EDUCATION IN THE UNITED STATES AND CANADA

THIRTY-EIGHTH ANNUAL PRESENTATION OF EDUCATIONAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The Council's preliminary report on extension courses for practicing physicians appears in this issue. Comment on the approved schools and statistical data for the academic year 1937-1938 are presented in the customary manner. Also included are revised lists of hospitals approved by the Council for internships and residencies in specialties and schools for occupational therapy, physical therapy and clinical laboratory technicians. The Essentials of an Acceptable Medical School and the Essentials of an Acceptable School of Occupational Therapy are reprinted as recently revised.

Statistics are presented covering seventy-seven medical schools¹ in the United States and ten in Canada, 729 hospitals approved for internships, 451 hospitals offering approved residencies in specialties, six schools for the study of occupational therapy, thirteen schools for physical therapy technicians and 137 schools for clinical laboratory technicians. The factual study of extension courses for practitioners covers twenty-three of the twenty-four states visited since October 1937.

These data are based on official reports. Acknowledgment is tendered the officers of the institutions mentioned and others for their ready cooperation in supplying the material submitted in this presentation as well as other data furnished throughout the year to the office of the Council and the members of its staff on inspection or visitation, enabling the Council to maintain its medical student and hospital registers efficiently and to carry on its activities as outlined by the House of Delegates of the American Medical Association.

PRELIMINARY EDUCATION

Although many medical schools have additional requirements, the minimum standard of the Council since 1918 has been two years of college, including English, theoretical and practical courses in physics and biology and in general and organic chemistry, completed in institutions approved by accrediting associations acceptable to the Council. There are six such agencies, namely:

- Association of American Universities.
- North Central Association of Colleges and Secondary Schools.
- Middle States Association of Colleges and Secondary Schools.
- New England Association of Colleges and Secondary Schools.
- Southern Association of Colleges and Secondary Schools.
- Northwest Association of Secondary and Higher Schools.

For the guidance of admitting officers and prospective medical students, the Council publishes annually a compilation of colleges of arts and sciences approved by these bodies. For the year 1937-1938 there were 721 institutions included in the list as follows:

Association of American Universities.....	286
North Central	268
Southern	186
Middle States	132
Northwest	67
New England	47

Of those recognized by the Association of American Universities, all but twenty-one are approved also by

1. Includes three schools whose approval has been withdrawn and one school placed on probation. See footnotes to table 2, page 787.

their district agency. In the various groups this dual approval of 265 institutions is distributed as indicated below:

North Central	100
Middle States	62
Southern	55
New England	31
Northwest	17

These five regional associations of colleges referred to cover among them the entire United States with the exception of the far southwestern section of the United States. Institutions in this territory can secure only the approval of the national group—the Association of American Universities.

Prospective medical students do well to secure their premedical training in colleges that are included in this list. Otherwise they may find it difficult or impossible to enter the medical school of their choice; for, while there is no inviolable rule excluding applicants from

TABLE 1.—State Requirements of Preliminary Training

Two Years of College		
Alabama	Maine	Oregon
Arizona	Maryland	Pennsylvania
Arkansas	Massachusetts	Rhode Island
Colorado	Michigan	South Carolina

Iowa	New York	West Virginia
Kansas	North Carolina	Wisconsin
Kentucky	North Dakota	Wyoming
Louisiana	Oklahoma	
One Year of College		
California		Connecticut
High School Graduation or Its Equivalent		
Missouri	Nebraska	Ohio

unaccredited colleges, officials, in selecting from so large a number, give the preference to those whose preparation has been received in institutions which are known to conform to accepted standards. Of students from other institutions, they exact, both qualitatively and quantitatively, a higher performance. Since success in the medical curriculum demands more than average intelligence and industry, the college student who cannot place himself in the upper third of his class should seriously question the advisability of starting on a medical career. In 1931 the Association of American Medical Colleges passed a resolution recommending the use of aptitude tests as an additional guide in the selection of students. Accordingly, the majority of schools base their decisions in part on the medical aptitude scores and in part on college grades.

The Council does not specify the courses which should be taken in secondary schools or those which should be chosen as electives in colleges. To some extent the candidate should follow his own interest but should obtain a general education which is as broad as possible.

(Continued on page 790)

TABLE 2.—Statistics of Recognized Medical Schools in the United States and Canada

Marginal No.	Name and Location of School	1933-1939 Prerequisite by Years	Length of Course, Academic Years	Students by Classes, Session 1937-1938					Graduates Since July 1, 1937	Session 1938-1939		Applications for Admission to the 1st Year Will Be Received Until	Executive Officer	Marginal No.

* Approval withdrawn June 11, 1938, without prejudice to the students then enrolled. This protection was also extended to the entering class of 1938-1939.

** Approval withdrawn Oct. 11, 1939, without prejudice to the students then enrolled. On June 6, 1937, protection was extended to students who may be enrolled in the first year class in 1937-1938.

On February 13, 1938, this protection was extended to the entering class of 1938-1939.

† On probation from June 6, 1937.
‡ Enrollment not on above table by classes for the two medical schools of the University of Chicago.
§ Fifth year (internship) enrollment not included in the total column.

§ Sixth year enrollment: Alberta, 31; Queen's, 52; Western Ontario, 34; Toronto, 113.

#Students admitted at different times of the year: Stanford, second year January 3; Northwestern, beginning of any quarter; Kansas, February 6, 1939; Minnesota, January 5; Tennessee, Sept. 22. Dec. 30, 1938 and March 20, 1939.

Place of Students

[illegible]

(Continued from page 785)

While the minimum requirement is two years, three years or more in college is recommended. For the session 1938-1939, fifty-eight of the seventy-seven medical schools in the United States have adopted preliminary requirements in excess of the minimum; i. e., five require a degree, forty-five require three years, one requires four years, five schools will admit students with three years of college work if the baccalaureate degree is conferred in absentia at the end of the first year in medicine, and two schools have a requirement equivalent to two and one-half years. Only nineteen schools have a stated two year requirement. Actually, however, most of their students enter with a preliminary training far in excess of the prescribed minimum. The general trend toward a requirement of three or more years of college work seems to be due to two factors; first, a desire for more thorough grounding in all the branches of chemistry and, second, a desire for a greater familiarity with nonscience subjects, such as literature, history or economics, than can be secured in two years of college.

The medical schools in Canada vary in their preliminary requirement. One requires a degree for admission to a five year course; four have a six year medical course preceded by senior matriculation which is equivalent to the work of the first year in a college of arts; one school requires one year for entrance to a five year medical course; three require two years, and one has a three year prerequisite.

A table appears later in this study recording the number of graduates of 1938 holding baccalaureate degrees (table 13). Similarly, mention is made of those who have received the degree of B.S. in medicine.

While the two year college prerequisite has been exacted by the Council for twenty years, there are still five states which have not revised or amended their statutes to conform, although these states rarely license other than graduates of approved schools. The pre-medical training required in each state is shown in table 1.

LENGTH OF MEDICAL COURSE

The medical course in the United States in general covers four academic years of approximately thirty-two weeks each. Fifty schools offer such a course. A few schools, namely the Universities of Northwestern, Minnesota, Duke and Tennessee, operate to some extent on the quarter system permitting a student by utilizing the summer months to decrease the length of time necessary to obtain his degree. A considerable number of the students of these schools do not elect to study during the summer months. The medical schools of the University of Chicago are operated on a plan of individual promotion permitting a student to advance as rapidly as he desires but the great majority complete the course in twelve quarters.

Fifty-five schools require a four year course, while twelve require four years of systematic instruction followed by a fifth year spent as an intern or in research work. Ten schools offer only a two year course.

Five of the medical schools of Canada offer a five year course, four have a six year course and one offers courses in the medical sciences only which are covered in two years. Four Canadian schools require an internship for graduation. These data are shown in table 2.

ESSENTIALS OF AN ACCEPTABLE MEDICAL SCHOOL

The Essentials of an Acceptable Medical School were recently revised and ratified by the House of Delegates at its 1938 session. They are published in full on pages 810 to 812. The principal change is the recommendation that medical schools not already doing so select their beginning students from among those having three years of college work rather than the minimum requirement of two years. This recommendation was based on a study made in 1937 showing that more than half of the students (3,181) admitted for the session 1936-1937 had a college degree before beginning medicine and 32 per cent had more than four years, leaving only 12 per cent with the minimum of two years. Furthermore, seven schools have raised their requirement for the session 1938-1939 from two to three years, namely Loyola, Iowa, St. Louis, Syracuse, South Dakota, Texas and Marquette. Fifty-eight of the seventy-seven medical schools in the United States now have a prerequisite of more than two years of college. Of the remaining nineteen, Minnesota and Oklahoma have announced that beginning in 1939-1940 three years will be in force.

MEDICAL CURRICULUM

The standard curriculum recognized by the Council on Medical Education and Hospitals and contained in its Essentials of an Acceptable Medical School consists of from 3,600 to 4,400 hours, distributed as from 900 to 1,100 hours a year and grouped under nine headings; namely, anatomy (including embryology and histology); physiology; biochemistry; pathology, bacteriology and immunology; pharmacology; hygiene and sanitation; general medicine; general surgery, and obstetrics and gynecology. A certain percentage of hours of the whole number of hours in the courses is required in each of these groups.

DEVELOPMENTS IN MEDICAL EDUCATION

Reports from a large number of medical schools indicate that, as a result of the Council's survey, substantial improvements have been and are being made in faculty personnel, student selection, clinical facilities, buildings and equipment. Nineteen schools have reported budget increases which average \$43,300. During the last four years the following institutions have greatly improved their physical plant: Alabama, Medical Evangelists, Georgia, Illinois, Indiana, Maryland, New York Medical College, Syracuse, North Carolina, Ohio State, Pittsburgh, Vanderbilt and Medical College of Virginia. Several other schools have plans outlined for additions to their physical plant.

MEDICAL SCHOOL SURVEY

The Council is now preparing a final report of the survey which will present a fairly comprehensive review of medical education based on the extensive data collected during the past three or four years. Such a commentary will doubtless be a valuable source of information to all who may be interested in medical teaching and will constitute a permanent record of the Association's most important contribution in the field of professional education. Confidential reports in graphic form have been sent to the schools visited. From these pattern maps, officers of an institution may learn where their school stands in relation to other schools with

respect to about 100 items used as a basis for comparison. The survey has revealed certain weaknesses in the organization and administration of a number of schools. Where unsatisfactory conditions have been found a warning has been given that improvement must be made within a limited time if the Council's approval is to be continued. The stimulating effect of such counsel is noticeable. Many of the schools will be revisited during the coming year in order to evaluate progress.

SCHOOLS OF THE BASIC MEDICAL SCIENCES

In the United States there are ten schools which offer only the first two years of the medical curriculum. For the most part these schools are located in smaller communities where clinical material is so scarce that satisfactory teaching of clinical medicine would be utterly impossible. In many instances, facilities do not exist for the satisfactory teaching of such subjects as physical diagnosis and gross pathology, which involve the use of clinical material. The same is true of the introductory courses in medicine and surgery, which commonly form a part of the second year schedule. Prolonged study of the problem led to the adoption in February 1937 of the following policy:

Following the recent survey of the medical schools it was decided that, effective July 1, 1939, the Council will publish a list of schools which teach acceptably gross and microscopic anatomy, biochemistry, physiology, pharmacology, bacteriology and pathology, even though they do not offer a full course leading to a medical degree.

The acceptance of courses involving the use of clinical material shall be left to the discretion of the faculties which admit to advanced standing students transferring from approved schools of the basic medical sciences.

Surveys of the clinical courses and facilities will be made by the Council and reported to the individual medical schools on request.

STATISTICS OF MEDICAL SCHOOLS

The medical schools approved by the Council on Medical Education and Hospitals of the American Medical Association during 1937-1938 are listed in table 2, pages 786 and 787 and contain figures regarding the premedical requirement for the session 1938-1939, the length of the medical course by years, enrolment by classes for the session 1937-1938, including fifth year students interning or engaged in research, the number of graduates since July 1, 1937, dates of the beginning and ending of the forthcoming session and the month until which applications for admission to the freshman class are received. Changes in the classification that have taken place since the publication of the educational statistics in 1937² can be noted in the footnotes at the bottom of the table and refer to those schools which are marked by asterisks preceding the name. Also contained in the footnotes are references to the fifth and sixth year enrolments and those schools which admit students at varying times during the year. The two medical schools of the University of Chicago do not report their students by classes and in this tabulation, therefore, only the total enrolment is given.

The data presented in this table constitute the basis also for several of the subsequent tabulations and beginning on page 815 are given historical information and essential facts concerning the schools arranged by states.

Seventy-seven institutions in the United States and ten in Canada are listed. All but four of these schools

at the present time enjoy the approval of the Council. In eighty-five schools, 6,429 freshmen students were enrolled, 5,852 sophomores, 5,528 juniors, 5,561 seniors, 392 fifth year and 230 sixth year students during the session just ended. In the two medical schools of the University of Chicago 549 students were enrolled, making a total of 24,541 in the eighty-seven schools listed. There were in the United States 5,791 freshmen, 5,225 sophomores, 4,986 juniors, 5,036 seniors and the 549 students of the University of Chicago, a total of 21,587. The total students registered by classes in the United States was 21,038. The enrolment in the ten two year schools in the United States was 526, of which 289 were freshmen and 237 sophomores. The enrolment in the ten Canadian schools was first year 638, second year 627, third year 542, fourth year 525, fifth year 392 and sixth year 230, a total of 2,954. The 24,541 medical students enrolled do not include 1,132 fifth year students in the United States interning or engaged in research and 123 in Canada interning as a requirement for the degree of Doctor of Medicine.

Since July 1, 1937, 5,691 received M.D. degrees, 5,194 from schools in the United States and 497 from Canadian institutions.

In addition there were 125 part-time, 376 special and 722 graduate students studying in medical schools.

Eleven medical schools had an enrolment of less than 100 students. None of the schools comprising this figure give the complete medical course. Fourteen schools matriculated fewer than 200 but more than 100, twenty-nine less than 300, fourteen fewer than 400, thirteen fewer than 500, and four less than 600. Two schools matriculated more than 600. The smallest enrolment (thirty-one) was at the University of South Dakota School of Medical Sciences, where seventeen freshmen and fourteen sophomores matriculated. This school does not offer the complete medical course. The greatest number (811) were enrolled in the University of Toronto Faculty of Medicine, which has a six year course including premedical subjects. The corresponding high figure among schools in the United States was 634 at the University of Illinois College of Medicine. The lowest enrolment among four year medical colleges in the United States was 106 at the Woman's Medical College of Pennsylvania. Among coeducational four year schools, Albany Medical College enrolled the smallest number of students, 110. Howard University College of Medicine graduated twenty-two students, the lowest number. The two schools that enrolled the fewest students had twenty-five graduates respectively. The school graduating the greatest number was Rush Medical College, which awarded 168 diplomas. The majority of schools will begin the session 1938-1939 about the middle of September and end early in June.

Of seventy-four schools that replied to the inquiry regarding the month until which applications for admission to the first year class will be received, two replied January, three February, twelve March, eight April, four May, nine June, eight July, five August, twenty-one September and one October and November.

The name of the dean or administrative officer of each institution is also given in table 1.

BIRTH PLACE OF STUDENTS

In table 3, pages 788 and 789, the birth state of students in attendance in medical schools during 1937-1938 is shown by schools. The state furnishing the greatest number of students, according to state of birth,

2. J. A. M. A. 109:660 (Aug. 28) 1937.

was New York with 3,063, followed by Pennsylvania with 1,926, Illinois with 1,488 and Ohio with 1,138.

From the twelve states in which no medical schools are located there were enrolled as students the following:

	Enrolled	Number of Schools
Arizona	41	22
Delaware	41	19
Florida	132	28
Idaho	102	34
Maine	105	36
Montana	105	35
Nevada	22	13
New Jersey	806	65
New Mexico	30	21
Rhode Island	118	35
Washington	274	46
Wyoming	25	15
Total	1,801	

There were 181 born in the United States territories and possessions studying in forty-four schools in the United States and three in Canada. In addition, 2,564

TABLE 4.—Students Classified by Birth Place

State	Schools	Attending School in State of Birth	Birth Place Elsewhere

Wisconsin	2	351	271
Canada	10	2,435	519
Totals	87	13,961	10,580

students of Canadian birth were also studying medicine, 129 of whom were matriculated in forty-four schools in the United States and 2,435 in the ten Canadian medical schools. Eighteen students of Canadian birth were registered at the College of Medical Evangelists and thirteen at Wayne University College of Medicine. Students born in New York were enrolled in all but seven schools. Pennsylvania was represented in all but sixteen schools. Residents of New Jersey, which has no medical school, were admitted in all but twenty-two schools.

In table 4 the classification of students is extended further by birth place, indicating that 13,961 are studying in the state of their birth and 10,580 elsewhere. This is particularly significant in Illinois, where, of the 2,144 students in five schools, 1,035 were born outside the state. More than 900 born elsewhere are studying in Pennsylvania, while of 2,534 studying in New York,

830 were born elsewhere. Altogether, 43.3 per cent are studying in schools located in other than their birth state. Eliminating the 1,801 born in states having no medical school, there are still 8,779 of the total number of students, 24,541, studying outside their birth state.

A perusal of table 4 will show many instances wherein the number studying elsewhere far exceeds the number attending school in the state of birth. It also shows some states in which the contrary is the case, notably Arkansas, Georgia, Indiana, Iowa, Kansas, Minnesota, Ohio, South Carolina and Texas.

One may not conclude that all of those attending schools outside the state in which they were born are nonresidents, but since requirements for "residence" differ widely among the states comparable figures based on residence are not obtainable.

There were 569 students of foreign nativity pursuing courses in sixty-six institutions in the United States. Altogether, seventy-seven countries were represented. The greatest number (sixty-seven) came from Russia; forty-nine were born in China, forty in Germany and Italy respectively, thirty-six in Poland, twenty-five in England, twenty-one in the British West Indies, nineteen in Mexico, eighteen in Cuba, seventeen in Japan, fifteen in India, thirteen in Austria, twelve in Greece and eleven in Hungary. From all other countries there were less than nine. Forty-two students were admitted to the College of Medical Evangelists, which educates mainly medical missionaries. These students represented twenty-one countries. Thirty-five students were admitted to the University of Illinois College of Medicine from fifteen countries, and twenty-three from seventeen countries went to Harvard and the same number from fifteen countries to the Hahnemann Medical College. It may be presumed that many of these are now citizens of the United States.

RESIDENT AND NONRESIDENT STUDENTS

Table 5 gives for each medical school the number of resident and nonresident students according to the individual school's definition of the word "resident." This table is being reproduced for the second time. Among state universities, as well as other schools, there is a variation in the definition of the term. In some universities this is determined by the legal or permanent residence of the student, parents or guardian only, while in some schools continuous residence for six months one, two or three years just prior to the student's application for enrolment is also required. Others require the student to be a voter; parents' home in the state established prior to beginning of premedical work; the student is a taxpayer or a dependent of a taxpayer, regardless of whether he resides in the state; self-supporting student, and each case determined by attorney after consideration of birth, citizenship, residence of parents, and so on. Of these methods the most common is the determination of residence by ascertaining whether the student, parents or guardian has been a bona fide resident for a period not less than six months. This requirement is in force in sixteen universities. In most schools also a student coming into the state for educational purposes only and establishing residence would not be considered a resident. Among other than state universities the term "resident" is defined mostly by the home address of the student or the legal residence of the parents or guardian. Two such schools did not reply to our inquiry, while in one school a student is considered a resident if he lives in the state.

On the basis of these factors, in the seventy-seven approved medical schools in the United States there were 13,518 students reported as residents and 8,069 as nonresidents, a total of 21,587 in the United States. The state university enrolling the greatest number of

Among other than state universities it is of interest to note the resident and nonresident enrolment. Many of the schools draw their enrolment from residents of the state. This is particularly true at Southern California, Stanford, Emory, Wayne, Long Island, Buffalo, New York Medical College, New York University, Syracuse, Cincinnati, Western Reserve, Pittsburgh and Baylor.

There is a similarity between the figures in this table and those of the preceding one classifying students by birth place. Excluding the Canadian registration given in table 4, there were 11,526 students attending school in the state of their birth and 10,061 elsewhere, as compared with 13,518 whose legal residence is in the state in which they are pursuing their medical courses and 8,069 classified as nonresidents.

* Excluding fifth or intern year students.

The ten schools in Canada reported 2,105 residents of Canada and 849 nonresidents. Their definition of a resident varied from students whose permanent address is within one of the provinces of Canada or the specific province in which the school is located to home address on registration and taxpayers. The greatest number of nonresidents in any one school were found at McGill University Faculty of Medicine (336), where only 141 residents of Canada were enrolled. This school has always obtained a large portion of its student body from the United States. At Dalhousie University Faculty of Medicine there were 113 nonresidents out of a student body of 178. All other institutions registered fewer than 100 nonresidents but more than twenty-five with one exception—the University of Saskatchewan School of Medical Sciences—with only two out of an enrolment of forty-seven.

Comparing the figures for Canada with those in table 4, classifying birth place reveals, as in the United States, somewhat similar figures: 2,435 born in Canada and 519 elsewhere, compared with 2,105 residents and 849 nonresidents.

nonresidents was the University of Tennessee College of Medicine, which had 222 residents and 215 nonresidents, while at Ohio State University College of Medicine and the University of Texas School of Medicine no nonresidents were registered, and only one of 633 students of the University of Illinois College of Medicine was a nonresident.

SCHOOLS, STUDENTS AND GRADUATES BY STATES

Medical schools are located in thirty-six states and the District of Columbia. In table 6 are tabulated the number of schools, students and graduates by states. New York, with the largest number of schools, nine, naturally had the greatest number of students and graduates, 2,534 and 583 respectively. Pennsylvania with six schools had 2,323 students and 601 graduates. Illinois with five schools, 2,144 students and 626 graduates, ranks third, while Massachusetts with three schools, 1,138 students and 287 graduates and California with four schools, 1,058 students and 271 graduates complete the group of states having a medical school enrolment over 1,000.

In the seventy-seven medical schools in the United States, including those that offer only preclinical courses, there were 21,587 students and 5,194 graduates. Students interning as a requirement for the degree, or fifth year students, are not included in this figure. Neither are part-time, special and graduate students.

The greatest number of graduates in any one state were the 626 who completed their courses in Illinois schools. New York with four more schools than Illinois had forty-three fewer graduates and Pennsylvania with one more school had twenty-five fewer graduates than Illinois and eighteen more than New York. Three other states had more than 200 graduates. Eleven states had more than 100 but less than 200 graduates. All others had less than 100.

REQUIRED HOSPITAL INTERNSHIPS

The medical schools and licensing boards requiring or planning to require a hospital internship for the M.D. degree and state licensure, respectively, are shown in tables 7 and 8. The effective date of the requirement is shown in both tables. Thirteen schools in the United States and four in Canada make the internship a prerequisite for a degree. A few of the medical schools will accept research or other clinical work in lieu of hospital service. Since 1915 the M.D. degree of the University of Minnesota Medical School has been

conditioned on an internship. Rush Medical College, which has required the internship for the M.D. degree since 1919, and the School of Medicine of the Division of Biological Sciences, University of Chicago, since 1930, discontinued this formal requirement in 1936. McGill University Faculty of Medicine reorganized its medical curriculum into a course of five years, including an internship replacing the former course spread over

five academic years of seven and a half months each by a course covering four years of nine months. The fifth year may be spent in an internship in an approved hospital or in further medical study at McGill or at another medical school approved by it. The changed curriculum was inaugurated for the freshman class of 1936-1937. It will not affect the students who began their course under the former system.

Duke University School of Medicine grants the degree after completion of the senior year, but all graduates are required to spend at least two years in hospital or laboratory work after graduation.

As revealed in table 8, twenty states, Alaska and the District of Columbia require that applicants for licensure shall have completed a hospital internship. The first state to adopt this requirement was Pennsylvania in 1914. The New Hampshire law became effective Jan. 1, 1938, while in Alabama and Louisiana it will be in force after Jan. 1, 1939.

While some of the medical schools and licensing boards have their own list of hospitals acceptable for intern training, generally the Council's list of hospitals approved for internships is followed. A revised edition will be found beginning on page 822.

During 1937-1938 there were 1,132 students of the United States and 123 in Canada reported as interning, a total of 1,255.

GRADUATES AND INTERNSHIPS

In table 9 are enumerated the graduates of the United States and Canada from July 1, 1936, to July 1, 1937, who have served or are still engaged as interns. Included also are figures for those schools which require the internship or other acceptable clinical work as a requirement for graduation. There were 5,852 fifth year students or graduates interning, the majority commencing the internship July 1, 1937, and ending July 1, 1938. The number of graduates and those who completed the medical course during the period July 1, 1936, to July 1, 1937, was 5,946; 4,760 graduates of medical schools and 1,186 fifth year students. Of these, ninety-four, 1.6 per cent, either were not successful in securing or did not desire internships. Several of the fifth year students satisfied this requirement by research or other clinical work. These 4,760 graduates and 1,186 intern students represented 4,383 graduates and 1,064 intern students of the United States and 377 graduates and 122 intern students in Canada. In the Canadian schools, of the 499 graduates or intern students, 467 were serving internships and thirty-two are unaccounted for.

Of the 5,852, 1,058 in the United States and 122 in Canada were completing the fifth year requirement of the schools they attended in order to obtain the M.D. degree, a total of 1,180.

With the exception of one, every school in the list had more than 90 per cent of its graduates serving internships and in fifty schools 100 per cent interned. Excluding those schools that require the internship for graduation, 98 per cent of all graduates here listed have obtained or are obtaining this added experience.

DISTRIBUTION BY SEX

Students and graduates in the United States and Canada classified by sex are shown in table 10. Seventy-seven schools had both men and women students, of which sixty had women graduates. Women were enrolled in nine of the eleven schools offering only the first two years of the medical course in the United States

and Canada. Altogether there were 23,234 men and 1,307 women students, and 5,439 men and 252 women graduates. Of these, 20,426 male students and 4,957

enrolled in the seventy-eight coeducational institutions in the United States and Canada and four graduates from sixty colleges.

WOMEN IN MEDICINE IN THE UNITED STATES

During 1937-1938 there were 1,161 women studying medicine in the United States, forty-eight more than during the session 1936-1937. The percentage of women

to all students for the academic year 1937-1938 was 5.4. There were 237 graduates, one less than last year. Of the women matriculants, 106 were in attendance at the one medical college for women, while 1,055 were matriculated in seventy-eight coeducational schools. From the Woman's Medical College twenty-five were graduated, while 212 secured their degrees from coeducational institutions. These data are given in table 11. Of interest also is the fact that thirteen schools enrolled more than twenty-five women. In the fourteen years since 1925, 3,008 women have graduated in medicine. The Council's list of hospitals approved for internships includes over a hundred hospitals offering about 250 internships open to women. Statistics are at present being compiled of the number of women physicians by county and state, based on the data included in the American Medical Directory, 1938 edition. This study has revealed that there are 7,470 women physicians in the United States.

PART-TIME, SPECIAL AND GRADUATE STUDENTS

In addition to the regularly enrolled students, there were 1,223 part-time, special and graduate students pursuing medical subjects in forty-nine medical schools in the United States and five in Canada. This group consists of 125 part-time, 376 special and 722 graduate students. These data will be found in table 12.

The part-time students were enrolled in twenty-five schools, twenty-two in the United States and three in Canada. The largest group enrolled in any one school was sixteen studying at the University of Buffalo School of Medicine. Thirteen were registered in New York University College of Medicine and twelve at St. Louis University School of Medicine. Less than eight were enrolled in twenty-one schools.

The 376 special students represented twenty-nine schools in the United States and three in Canada. The greatest number (111) were at Northwestern University School of Medicine; at the University of Toronto Faculty of Medicine sixty-eight were in attendance; the School of Medicine of the Division of Biological Sciences of the University of Chicago had thirty-one, Vanderbilt twenty, North Carolina and Illinois nineteen.

Students pursuing subjects leading to higher degrees were studying in twenty-eight schools. Altogether there were 722 such, of whom more than sixty were studying in each of four schools, the greatest number (141) having been enrolled at New York University.

The following schools matriculated these three types of students: Universities of Iowa, Kansas, Johns Hopkins, Wayne, New York University, Buffalo, North Carolina, Vanderbilt and Toronto.

Among Canadian schools seven part-time, seventy-one special and sixty-nine graduate students were enrolled.

GRADUATES WITH BACCALAUREATE DEGREES

From the figures contained in table 13, it can be noted that 3,685 of the 5,691 graduates of medical schools for the session 1937-1938 also hold baccalaureate degrees. Only five schools in the United States required a degree for admission for the session, one required four years, four schools admitted students with three years of college work provided the baccalaureate degree would be conferred in absentia at the end of the first year in medicine, thirty-nine required three years, one school had a requirement equivalent to two and one-half years and twenty-seven exacted the two year requirement. Twenty-three schools offer a B.S. in medicine degree at some time during the

medical course—seven at the end of the first year, thirteen after two years in medicine and two after three years, while in one school it can be obtained at any time during the medical course. All the graduates of Stanford, Johns Hopkins, Wayne, Cornell, New York

University, Western Reserve, Oregon, Jefferson, Vanderbilt and Wisconsin held baccalaureate degrees. Four of these schools—Stanford, Wayne, Oregon and Wisconsin—do not have a degree requisite, their requirement being three years.

SCHOOLS, STUDENTS AND GRADUATES IN THE UNITED STATES, 1905-1938

The number of medical schools, students and graduates in the United States for each five year period from 1905 to 1920 and for each year since is shown in

table 14. The total number of undergraduate medical students for the college session 1937-1938 was 21,587. In 1905 in the 160 schools then existing there were 26,147 students. This tabulation includes data for only those taking medical courses leading to the M.D. degree. They do not include part-time and special students even though their work may later be accepted for the M.D. degree, since they are reported as part-time and special students and not candidates for a medical degree. Omitted from these figures also are university graduate students majoring in the medical school but not candidates for the M.D. degree. In the ten years from 1910 to 1920 there was a steady decrease in the enrolment, while from 1921 to 1935 there was a continuous increase. In 1938 the enrolment decreased by 508 from the preceding year. The number of students admitted in 1938 was 977 fewer than in 1936 and 1,301 fewer than in 1935. In 1935 the Council advised against the admission of larger classes than can be accommodated or than can reasonably be expected to satisfy approved scholastic standards. Many of the schools, as will be noted in table 14, heeded this declara-

* Includes figures for schools offering preclinical courses.

tion and decreased their freshman enrolment in the interest of better medical education, and others are planning to do so in the future. This may not mean any decrease in the number of medical graduates, because more careful selection will doubtless decrease the number of students who fail to complete their course because of poor scholarship.

Again referring to table 14, it will be noted that the total number of graduates was 5,194, which was 183 fewer than were graduated in 1937. With the exception of the slight decrease in the number of graduates in 1933 as compared with previous years, there was a steady increase from 1926 to 1937 and in 1938 a decrease. In the seventy-seven recognized medical schools in the United States during 1937-1938 there were 21,587 students, including those having an incomplete course, and 5,194 graduates.

STUDENTS BY CLASSES, 1930-1938

The number of students in the various classes of the medical schools in the United States for each session from 1930-1931 to 1937-1938 inclusive is shown in table 15. The total attendance for the first year for the session 1937-1938 was 5,791, 119 fewer than the number enrolled for the session 1936-1937. Since the

session 1933-1934, when there were 6,457 enrolled, there has been a reduction in this class of 666. The total attendance for 1937-1938 for the remainder of the classes was respectively 5,225, 4,986, 5,036 and 1,132, a total of 22,719. The two medical schools of the University of Chicago are not operated under the

promotion by class system but on an individual plan. It is not possible for the schools to report their students in this manner and accordingly they are not included in the figures by classes, but their enrolment is included in the total. At the School of Medicine of the Division of Biological Sciences of the University of Chicago there were 287 and 262 at Rush Medical College, a total of 549. There were 631 fewer students enrolled than in 1936-1937, 1,058 fewer than 1935-1936. The sophomore enrolment decreased forty-four, the junior

enrolment 154, the senior enrolment 122 and the fifth or intern year students 123. These figures are exclusive of the figures for the two schools referred to.

NEGRO STUDENTS AND GRADUATES

The Negro medical students for the session 1937-1938 enrolled in the United States and Canada are recorded by classes in table 16. Totals for the session 1936-1937 are shown for comparison. There were 372

such students and sixty-one graduates. The total number of students for 1937-1938 was the same as for 1936-1937, but there was a decrease of twenty-three in the number of graduates this year. The only medical school for Negro youth, Meharry Medical College, matriculated 206 students and had thirty-five graduates. At Howard University College of Medicine they comprise a majority of those in attendance and for this session 121 students of a class of 131 and eighteen of the twenty-two graduates were Negroes. These two schools graduate the majority of the Negro students. All other schools (six) graduated eight. In eighteen schools in the United States, exclusive of Meharry and Howard, forty students were enrolled. There were five Negro students in two Canadian schools. The enrolment by classes in all schools was first year 126, second year 104, third year seventy-seven, and fourth year sixty-four, a total of 372, including a fifth year student in a Canadian school. In 1936-1937 corresponding figures were 130, eighty-eight, seventy, eighty-two, 372. The freshman enrolment decreased four, the sophomores increased sixteen, the juniors increased seven and the seniors decreased eighteen. A study is being made of the Negro physicians in the United States by state and county from the data included in

the 1938 edition of the American Medical Directory. A total of 3,392 Negro physicians are listed in the Directory.

FEES

In table 17 the eighty-seven medical schools of the United States and Canada have been grouped according to the tuition fees charged. To arrive at the figures listed, an average was computed of the resident fees for each school. Included in these fees are the various minor charges, such as for matriculation, breakage, diploma and graduation. Four schools have fees under \$100. These were Louisiana State University, University of North Dakota, University of Oklahoma and University of Texas. The thirteen schools having fees over \$500 are College of Medical Evangelists, Yale, George Washington, Johns Hopkins, Columbia, Cornell, Long Island, New York Medical College, New York University, Syracuse, Buffalo, Hahnemann and Pennsylvania. Thirty-one schools in the United States and five in Canada made an additional charge for non-residents ranging from \$50 by the Universities of Minnesota, Mississippi, Cincinnati (nonresidents of Cincinnati) and Virginia to \$300 exacted by the University of California and Louisiana State University and \$425 by Harvard University.

Table 17 compared with a similar compilation in the 1937 educational statistics indicates that this year there are only twenty-three schools in the \$200 to \$300 bracket, whereas in 1936-1937 there were twenty-seven; likewise in the \$300 to \$400 group there are sixteen, as compared with fifteen for the last college

session; in the \$400 to \$500 bracket the figure increased one and in the \$500 or over class there are now thirteen schools, an increase of two.

The lowest nonresident fee in the United States was \$50, as has been indicated. One school in Canada has a nonresident fee of \$5 for the first year and \$10 for the second, third and fourth years. Eleven schools in the United States and Canada have a nonresident fee

CITIZENS OF THE UNITED STATES ENROLLED IN
FACULTIES OF MEDICINE ABROAD

A study of the number of citizens of the United States pursuing medical courses in faculties of medicine abroad has been carried on by the Council since 1931, when it became evident that great numbers were going to Europe to study. Table 18 lists the institutions in which such students are enrolled. This tabulation

of \$100 or less, sixteen schools between \$100 and \$200, six schools between \$200 and \$300, and one has a fee of \$425.

The data and text regarding table 5 listing the number of residents and nonresidents and the definition of the term resident may be of interest in connection with the fees charged nonresidents. The fees are not listed in these statistics by individual schools other than in the descriptions beginning on page 815. The fees there given are for the session 1938-1939.

The average resident fee charged in medical schools of the United States was \$342.

covers the academic year 1937-1938. In a few cases, because figures were not available, it was necessary to reproduce figures from previous sessions for several schools known to have citizens of the United States enrolled. Including these figures, there were 1,346 students and 318 graduates or those who completed their training in eighty-four institutions—seventy-eight schools in fifteen European countries, two in two South American countries and four in three countries of Asia. The files of the Association of American Medical Colleges indicate that the application record of many of these students show that they have made application

to medical schools in the United States without success. A study is also being carried on of the license record of foreign physicians.³

Table 19, recording the number of graduates of foreign medical faculties (representing both American and foreign born physicians) examined by licensing boards in the United States in eight years and the percentage failing, is of interest. In addition to the figures given

TABLE 19.—*Graduates of Faculties of Medicine Abroad Examined—1930-1937*

Year	Number Examined	Passed	Percentage Failed
1930.....	167	92	44.9
1931.....	138	91	42.4
1932.....	182	96	47.3
1933.....	200	129	35.5
1934.....	285	170	40.2
1935.....	437	303	30.7

1937.....	919	636	30.7

a number have been periodically licensed without examination—by endorsement of their credentials, which are equivalent to licensure in this country. In 1937, 238 were so registered. This table makes no differentiation between United States citizens and those foreign born. It might be assumed that some of those who began the study of medicine in 1930 are returning to the United States to practice. The figure also includes many refugees from Germany and Austria.

ity of new students going abroad to study are migrating to these two institutions. Fifty-three of the eighty-four institutions listed had less than five students. During 1937-1938, according to the reports furnished, there were 1,346 students as compared with 1,631 during 1936-1937, 2,052 in 1932-1933 and 710 in 1930-1931.

Conferences with the governments of many European countries together with resolutions by the Council and the Federation of State Medical Boards have resulted in a diminution in the number of American born students being accepted by European schools.

The House of Delegates of the American Medical Association in 1936 endorsed a resolution urging that graduates of medical faculties of other countries be expected to prove their fitness for medical practice by being in possession of a license to practice in the country of their graduation and a certificate of internship in a hospital approved for such training or complete the fourth year in an American class A medical school.

In 1938 the House of Delegates adopted a resolution urging an additional requirement of full citizenship in the United States of all applicants from abroad. Several of the licensing boards in the United States have adopted special rules regarding the admission of physicians with foreign degrees because no agency exists for the evaluation of such credentials. One state has amended its statute requiring foreign graduates to complete a year in a medical school or serve a hospital internship in this country. A few others have board

The enrolment of students in foreign countries for each session since 1930-1931 is shown in table 20. The largest numbers were enrolled in Austria, Germany, Italy, Scotland and Switzerland. The greatest number (249) in any one school was the enrolment of St. Mungo's College Medical School, Glasgow, followed by the School of Medicine of the Royal Colleges, Edinburgh, where 226 were enrolled. These are extramural schools and do not grant the M.D. degree. The major-

ruings requiring one or the other of these, several require citizenship, one state will not accept any graduates of foreign schools, and another requires the certificate of the National Board of Medical Examiners. Further, in order to maintain approval by the Council, hospitals in which these students seek internships may accept them only on the successful completion of parts I and II of the examinations of the National Board of Medical Examiners, and when suitable graduates of American schools are not available.

EDUCATION

Extension Training in 23 of 24 States Visited to Date *

Meeting Places	Instructors	Admission Requirements	Limitation of Classes	Registration Fee	Approximate Yearly Attendance	Miscellaneous Information
Varied	Out of state, in state and local M.D.'s	M.D.	No	No	680 (Annual Meeting)	Extension of graduate program projected to supplement training now being given; financed jointly by Med. Assn. and Dept. of Public Health
Hospital or Hall	Med. Sch. faculty members and in state and local M.D.'s	Co. Med. Soc. Membership	No	No	950	Budget for current year estimated at \$4,000; 300 physicians in state available as instructors
Hospital or Hall	1 out of state M.D., Med. Sch. faculty members and 11 in state M.D.'s	Co. Med. Soc. Membership	No	\$5	50	\$25 prize offered for best written review of course
Varied	In state M.D.'s	M.D.	No	No	...	
Hall	Out of state univ. prof.	Co. Med. Soc. Membership	No	No	..	Financed by State Dept. Pub. Health. Also series of 10 lectures on venereal diseases at U. Calif. Hosp. in San Francisco
Univ. Hosp.	Faculty members (22)	M.D.	No	\$20	40	Fee included meals and syllabus of lectures. State medical library with 2 sections offers package service to practicing physicians
Hospitals	Approximately 50 faculty members	M.D.	In Lab. and Ward Rounds 15 to 24	\$25	160	A physician may register for 1 morning and 1 afternoon course
Hosps. and Med. Schools	In state and local M.D.'s and faculty members	M.D.	Study groups from 5 to 10	\$10-15 (S. F.) \$2 (L. A.)	300	Fee includes cost of syllabus and membership in the Assn.
Med. College	Faculty membs. of 3 Med. Schs. give Fall Assemb. and 30 from Coll. Med. Evan. give Spring Clinics	M.D.	No	\$1.50	400-500	Exhibits, demonstrations and clinical pathologic conferences feature the Spring Clinics
Med. Sch.	Faculty members	M.D.	Yes	Varies	...	Opportunities for study in anatomy and other basic sciences
Hospitals, Med. Sch. and Hotel	Out of state, in state and local M.D.'s (Total approx. 40)	M.D.	No	\$2	245	St. Med. Soc. and St. Univ. Sch. of Med. jointly support. Denver Co. Med. Soc. and St. Med. Soc. maintain library for physicians in Denver
Hotel and Theater Auditoriums	Out of state M.D.'s (20)	M.D.	No	\$3	790	Next meeting (1939) to be held in Utah—subsequent meetings in other states
Hospitals	Out of state, in state and local M.D.'s (20)	M.D.	No	\$2	165	St. Med. Soc. and 4 local hospitals jointly support; Colo. St. Hosp. staff meets 1-4 times mo. for C. P. C.'s and reviews of neuropsychiatric exams. and treatment
Hotel	In state and local M.D.'s	M.D.	No	..	50	St. Med. Soc. jointly sponsors
Hospitals or Halls	In state M.D.'s	Co. Med. Soc. Membership	No	No	...	Instruction voluntary; handbook on diagnosis and treatment in preparation
Hospitals or Halls	In state and out of state univ. profs. (6)	M.D.	No	No**	115	Physicians in 11 counties in northern and northeastern Colorado enrolled
Univ. buildings and hospitals	In state and out of state M.D.'s and faculty members	M.D.	No	\$2	605	12 states represented; a permanent record system has been developed; 12 chairmen of symposiums in 1937
Univ. hosps.	Faculty members	M.D.	Yes	No	...	No formal p. g. courses; opportunities available for physicians of Conn.
Hospitals	In state and local M.D.'s	M.D.	No	No**	50	A monthly series of lectures on heart disease given in Fairfield Co. 1935
Co. Soc. choice	300 in state M.D.'s and univ. faculty members	Co. Med. Soc. Membership	No	No	..	Financed by St. Med. Soc.; teams of 3 to 6 M.D.'s available to any Co. Soc. on request
Co. Soc. choice	In state M.D.'s	M.D.	No	No**	..	Clinical instruction given in Chicago supplements short lecture courses arranged by field organizer, with Speakers' Bureau of St. Med. Soc. completing arrangements. A.M.A.'s Med. Lib. available to individual subscribers of A. M. A. publications; p. g. courses in urology and cardiovascular disease offered in Aug. and Sept. annually by Northwestern U. Med. Sch.
Research and Educational Hospital, Chicago	Faculty members of approved med. schs.	M.D.	18 each wk's. class	\$10**	65	
Univ. Med. Sch. and Hotel	Out of state, in state and local M.D.'s (6 out of state M.D.'s)	M.D.	No	No	500	Financed jointly by Univ. and Med. Assn.; facilities of medical school, including package medical library available to physicians; 2 wk. intramural courses offered by Univ. Dept. Obs. during 9 mos. of yr. (resident facilities for physicians)
Varied	Out of state and in state M.D.'s	M.D.	No	No**	...	Speuker's program prepared by Bureau of Maternal and Child Health of St. Bd. of Health; dir. of p. g. obs. education conducts circuit courses in Dist. Med. Soc's.
Hospitals	Out of state and local M.D.'s	M.D.	Small groups	No	200	One week course in Indianapolis attended by 12 physicians and financed by T. B. Assn.
Hotels and St. Univ.	Out of state, in state and univ. M.D.'s (Choice by vote of registrants)	St. Med. Soc. Membership	No	\$5, \$10	450	Financed by St. Med. Soc.; state med. libraries at Des Moines and Iowa City with package medical service

GRADUATE MEDICAL
Opportunities for Practicing Physicians to Engage in

State	Location of Course	Sponsoring Agencies	Director of Program	Subjects	Duration of Course	Time Given	Type of Instruction
Iowa (cont'd)	8 towns	St. Dept. Health and St. Med. Soc.	Chairman, Speakers' Bureau, St. Med. Soc.	Obstetrics and Pediatrics	1 day weekly 8 times	March, April and November (1937-38)	Lectures
Kansas	30 towns	St. Med. Soc. and St. Bd. of Health	Comms. of St. Med. Soc. and Secy., St. Bd. of Health	Obstetrics, Pediatrics, Syphilology, Cancer and T. B.	1 day weekly 4 times	June to September	Lectures
	Kansas City and Lawrence	St. Univ. Med. Sch.	Dean, Med. Sch.	General	3 days	Spring	Lectures, Clinics, Ward Walks
Kentucky	8 councilor districts (incl. Louisville)	St. Med. Assn.	Chairman, Comms. on Extension Course and P. G. Course in Dis. of Children	General and Pediatrics	Day and evening 1 day weekly 10 times	Varies April	Lectures

	Joplin	Jasper Co. Clin. Soc.	Secretary	General	1 day	Spring	Lectures
	30 towns in 9 councilor districts	St. Med. Assn. and Dept. of Health	Chairman, Speakers' Bureau, St. Med. Assn.	Obstetrics and Pediatrics	3 to 16 days in each dist.	Throughout year	Lectures, Manikin Demonstrations and Movies

EDUCATION—Continued

Extension Training in 23 of 24 States Visited to Date *

Meeting Places	Instructors	Admission Requirements	Limitation of Classes	Registration Fee	Approximate Yearly Attendance	Miscellaneous Information
Hotels, Hospitals and Schools	In state and univ. M.D.'s	M.D.	No	\$2**	345	St. Dept. of Health cooperates with T.B. Assn. in T.B. case finding studies and with St. Univ. in crippled children's program
Varied	Out of state and in state M.D.'s	M.D.	No	No**	855	St. U. Ext. Div. assisted in registering physicians for courses; annual meeting of St. Med. Soc. devoted in part to grad. instr., average attendance 750
Med. Sch. and Univ.	Out of state M.D. and faculty members	M.D.	75	No	75	Supervised clinical clerkships for 1 week projected
Available Auditoriums	In state M.D.'s	Co. Med. Soc. Membership	No	No	..	St. Bd. of Health, on request, furnishes programs on T.B., syphilis, pediatrics or obstetrics to county societies or councilor districts
Children's Free Hospital	11 local M.D.'s	M.D.	Yes	\$5	20	
Louisville City Hospital	Faculty members and local M.D.'s	Co. Med. Soc. Membership	No	No	160	Co. Soc. deposits books and periodicals and helps maintain Univ. Louisville Med. Sch. Library
Louisville City Hosp. and Univ. Clinics	Faculty members	M.D.	No	No	6	Two months postgraduate course for Negro physicians with supervised clinical experience in Univ. Clinics and wards; 8 accepted in medicine, pediatrics or obstetrics
Hospitals	56 M.D.'s of univ. faculties and in state M.D.'s	M.D.	No	No**	710	District medical societies choose subjects from list supplied; 5 divisional chairmen in charge of instruction; financed partly by St. Med. Soc.; Boston Med. Library is the home of Mass. Med. Soc.; library dues are \$15 per year
Med. Sch. and affiliated hospitals	Faculty members	M.D.	Yes	Yes (Varies with subject chosen)	..	Commonwealth Fund of New York subsidizes applicants approved on their merits for specially arranged courses
Med. Sch. and affiliated hosp.s. and clinics	Faculty members	St. Med. Assn. Membership	Yes	\$5	Varies	Bingham Associates Fund now offers fellowships to practicing physicians of Maine
Univ. hospitals and labs.	Faculty members	M.D.	Yes (Pre-clin. courses)	\$25 per mo. for special courses	485	Spring review courses of extramural fall instruction given; no fees; lecture notes published and available to registrants at \$1 per volume. Extramural courses accessible to majority of physicians in state. Out of state physicians may attend intramural courses given at Ann Arbor and Detroit; financed jointly by Univ. Mich., St. Med. Soc., St. Dept. of Health. At Detroit: Noonday Study Club weekly; annual 3 day lectures and cooperative programs with local hospitals sponsored by Wayne Co. Med. Soc.; County Society Library maintained, in part, at Wayne Univ. Coll. Med.
Hospitals	Faculty members and in state M.D.'s (Approximately 75 instructors)	M.D.	No	No	1,805 (Total)	
Hospitals when available	In state M.D.'s	M.D.	No	No**	315	
Study center, Univ. controlled Wards and Clinics	Faculty members, in state and out of state M.D.'s	Co. Med. Soc. Membership	15 to 25 (Accommodations for 78)	\$25	200	350 faculty appointments for 16 weekly institutes; since started 412 M.D.'s registered; out of state physicians may attend; Commonwealth Fund aids
Hospitals when available	Faculty members and in state M.D.'s	M.D.	No	\$1 to \$5	200	Intramural night courses in prev. med., T.B., x-ray diag. and allergy given once weekly for 8 or 17 weeks; fees \$5 and \$10 respectively; 56 registered
Univ. Med. Sch. and Hotels	Faculty members and in state M.D.'s	M.D.	No	No**	325	35 faculty members conducted first series of lectures on University campus
Available halls	Univ. professors	M.D.	No	\$3 to \$5	620	Commonwealth Fund, St. Med. Assn., St. Bd. Health jointly finance; Miss. Hosp. Assn. also cooperates; a field organizer and field clinicians are engaged
Hotel	Univ. faculty	M.D.	No	400	9 faculty members U. Tenn. Coll. Med. in 1937 and 15 from Tulane U. Sch. Med. in 1938 participated in meetings. Med. libr. serv. by St. Bd. Health, Jackson
Hospitals or Halls	Faculty members and in state M.D.'s	St. Med. Assn. Membership	No	No	County societies may request speakers on any subject—usually those of current interest chosen; financed by St. Med. Assn.
Hospitals or Halls	Full time univ. profs.	M.D.	No	No**	560 (1936-7)	Program to continue until physicians in all sections of state offered courses
Kansas City General Hosp.	Co. Soc. members (19)	M.D.	No	\$2 to \$10	Not yet available	County Medical Society maintains medical library in Kansas City General Hospital; course in psychoanalysis and a medical speakers clinic also included
Municipal Auditorium	Out of state and local M.D.'s	M.D.	No	\$5	300 and 1,000	Exhibits aid in financing; Kansas City Medical Journal publishes papers read annually; 250 M.D.'s are society members
Med. Sch.s. and Halls	Local M.D.'s	M.D.	No	\$10	203	141 members of Clinical Society conduct the clinics
Univ. Clinics and Hospitals	Faculty members	M.D.	25 15	\$100 \$50	...	Registrar accepts applications accompanied by \$10 registration fees
St. Mary's Infirmary	Med. Sch. faculty	M.D. (Negro)	50	No	50	Arrangements for informal instruction may be made on request to Dean, Med. Sch.
.....	M.D.	No	
.....	M.D.	
Varied	Out of state and in state M.D.'s	M.D.	No	No**	St. Med. Assn.'s Central Advisory Comm. now correlates all grad. activities in state; 100 Nebraska physicians available for teaching; St. Dept. of Health cooperates

GRADUATE MEDICAL
Opportunities for Practicing Physicians to Engage in

State	Location of Course	Sponsoring Agencies	Director of Program	Subjects	Duration of Course	Time Given	Type of Instruction
Nebraska (cont'd)	Omaha	Omaha Mid-West Clinical Soc.	Director	General	5 days	October	Lectures, Clinical Conferences, Discussions and Exhibits

EDUCATION—Continued

Extension Training in 23 of 24 States Visited to Date *

Meeting Places	Instructors	Admission Requirements	Limitation of Classes	Registration Fee	Approximate Yearly Attendance	Miscellaneous Information
Hotel	Out of state and local M.D.'s	M.D.	No	\$5	670	125 local M.D.'s are society members, many being on faculties of the two local medical schools. Med. Lib. serv. for physicians maintained at U. Nebraska
U. Nebr. and St. Joseph Creighton Mem'l Hospital	21 members of 2 Med. Sch. faculties	M.D.	10	No**	Includes round table discussions and mimeographed copies of lectures and demonstrations; 2 courses each year; T. B. case finding study with educational features in 5 cos.
Varied	Out of state univ. profs.	Co. Med. Soc. Membership	No (for 25 or more)	\$10	385	C.P.C.'s in Newark City Hosp., average attendance 100 M.D.'s; T.B. institutes yearly in Hudson Co. and occasionally elsewhere
Varied	Out of state and in state M.D.'s	M.D.	No	No**	500	Health Dept.'s field physicians offer informal instruction to practicing physicians
Hospitals	Hospital staffs	M.D.	No	No	Not yet available	Annual Clinical Conference
Hospitals and Halls	Med. Sch. faculty and in state M.D.'s	M.D.	No	No	2,000	St. Med. Soc. appropriated \$5,000 for grad. med. ed. during 1937-38; 5 obstetric courses financed by St. Dept. of Health
Hospitals or Med. Schools	Med. Sch. faculty or hospital staff members	M.D.	Groups of 4 to 6 each	Varies	Personal instruction in EKG and other subjects given at Syracuse, small groups instructed by professional teacher
Hospitals, Med. Schools or Halls	Med. Sch. faculty or hospital staff members	M.D.	Yes (Institutes)	No	375 (at Med. Centers)	Financed by St. Dept. Health which reimbursed registrants' travel and hotel expenses to medical center for 1 day "institutes"; estimated 5,400 attended over 2½ yrs. throughout the state
Med. School and Hospitals	55 faculty and guest M.D.'s	M.D.	Groups of 5 each	\$50	55	Medical school allots \$1,500 annually; library facilities open to physicians
Med. Soc. Audit., Med. Coll. Hosp. and Local Hosps.	Med. Coll. faculty and in state M.D.'s	M.D.	Short courses not limited; intensive long courses limited	\$0 to \$10 and \$20-\$100	175	Med. Soc. and Acad. Med. Library maintained for local physicians; Friday afternoon lectures on general subjects at Co. Med. Soc. building 1 day weekly for 20 times; special courses available at L. I. Coll. of Med.
Academy Bldg. and 18 hosps.	Out of state and in state M.D.'s	M.D.	No	\$3	500-500	Members demonstrate scientific exhibit; two thirds of registrants from Greater N. Y.; 17 states represented; all other Acad. activities without charge. Acad. cooperates with many medical and health agencies concerned with medical education in New York City
Academy Auditorium	Out of state and in state M.D.'s	M.D.	No	No	300	Thursday afternoons
Academy Auditorium	In state M.D.'s	M.D.	No	No	200	Includes round table discussions
Hosps., Med. Schs., Academy Auditorium	In state M.D.'s	M.D.	No	No	150-200	
Acad. Audit., Hosp., Health Dept. and Med. Sch. Clinics	In state M.D.'s	M.D.	No	No	95	Clinics held 2 days a week in 13 places, attended by 1 to 10 physicians in each clinic in 4 boroughs
Academy Auditorium	In state M.D.'s	M.D.	No	No	235	All lectures open to medical students; library of Acad. open to public, 60% of patrons being M.D.'s
Co. Soc. Audit.	Out of county M.D.'s	Co. Med. Soc. Membership	No	No	100	Course in public speaking, 1 night week Oct.-Dec. 1938, fee \$35; course in med. Italian, 3-4 p. m., 1 day week beginning 7/6/38, no fees; symposium on dermatology 11/14-17/38 for Co. Soc. members; medical library maintained in County Medical Society building
Metropolitan Hospitals	In state M.D.'s	M.D.	20-50	No	1,100	Co. Med. Soc. secretaries acted as registrars; hosp. comms. aided with local arrangements
Facilities of City Health Dept.	Local M.D.'s	M.D.	8	No**	60	Cooperative project with U. S. Public Health Service
Affiliated Institutes and Hospitals	Faculty members	M.D.	Yes	\$12-\$400	465 (Fig. for 1936-7)	See: Postgrad. Med. School's annual announcement for further details
Affl. Hosps.	Faculty members	M.D.	Yes	Varies	140 (Fig. for 1937-8)	Course in syphilology, Feb.-June, in coop. with U. S. Pub. Health Serv. and St. Dept. Health; 16 physicians registered in 1938; see: bull. for grad. and p. g. opportunities
Clinics and Hospital	Faculty members	M.D.	Yes	Varies	160 (Fig. for 1936-7)	See: Polyclinic Med. School's annual announcement for further details
Hotels and Halls	Out of state M.D.'s	M.D.	No	\$15	350	Lectures projected for rural areas with financial aid of medical and health agencies of North Carolina
Hotel and Hospital	Out of state and local M.D.'s	St. Med. Soc. Membership	No	No	St. Soc. P. G. Comm. cooperates with other agencies in state active in graduate education
Univ. and Hospital	Out of state M.D.'s and faculty members	M.D.	No	No	600 (Grad. sympos.)	Resident facilities offered prac. phys. at med. sch. for 1 to 2 wks. throughout year, limited to 2 phys.; fee \$10 wk. inc. board and room
Med. Sch.	Out of state M.D.'s	M.D.	No	No	125	Previous symposiums on tumors held at Wake Forest in 1934; financed by St. Med. Soc.
Hospitals and Halls	Out of state M.D.'s	M.D.	No	No**	430	Similar course in pediatrics is projected
Hospitals	Out of state and in state M.D.'s	M.D.	No	Seminar held yearly, using facilities of two local pediatric hospitals
St. Joseph's and Providence Lying-In Hosps.	In state M.D.'s	M.D.	No	No**	115	Providence hospitals' facilities used for C.P.C.'s, attended by 150 M.D.'s twice monthly, and for annual meetings of St. Med. Soc.; St. Med. Soc. Libr. maintained in St. Soc. building
Hotels and Halls	Univ. prof.	M.D.	No	No**	Course recently organized; all data concerning it are not available; St. Med. Assn. developing med. libr. at Seneca
Hospital	Out of state, in state and local M.D.'s	M.D.	No	\$2	100	Med. Coll. St. So. Car. and St. Med. Assn. jointly aid in this graduate assembly

* No organized training in Nevada; data on formal instruction in metropolitan areas not complete.
 ** Federal financing.

(Continued from page 801)

have aided materially in organizing field courses in eight states. Private and public hospitals have contributed their facilities in nineteen states, and medical schools have provided faculty, space and equipment in nineteen states.

Each state visited seemed to have a different manner of organizing and administering instruction for its own physicians. These differences seemed to be predicated on differing local and community conditions. Such factors as the proximity to medical centers, the proportion of rural and urban communities, the development of highways, the climatic conditions, and the ability of physicians to leave their practices for sufficient time to continue professional training had to be considered.

METHODS OF INSTRUCTION

In twenty-three states, opportunities were offered physicians practicing outside of metropolitan areas to continue their professional training.² Ten states have utilized a field secretary or organizer to determine the educational needs of extrametropolitan physicians and to aid materially in meeting these needs. Extension training in smaller cities or towns consisted of lectures illustrated by slides or motion pictures, demonstrations of cases, case finding clinics, symposiums with complete consideration of one subject and/or round table discussions.

Circuits of from five to six towns were sometimes chosen as training centers where each town was visited weekly from four to ten times. This was the method employed in ten states. One physician or a team of physicians would spend from one to two months in the

region of the circuit and then move on to a new area. This procedure requires permanent personnel, at least for the period of the course.

Another manner of offering instruction to extrametropolitan physicians, which is being used more frequently today, was the provision of prominent out of state or in state physicians for one or more meetings at fixed teaching centers as part of a continuous, planned, scientific and clinical program. Under this system physicians within convenient distances of the courses are offered the educational advantages of various medical centers brought to the vicinity of their practice. While local facilities may limit the kind of training offered, illustrated lectures, clinics, demonstrations, discussion groups, symposiums and clinical pathologic conferences have been undertaken with success. Hospitals usually offered the best facilities, but hotels have been used extensively, and halls in other buildings sometimes provided the only meeting places available.

Thirty-seven metropolitan centers provided graduate activities in seventeen of the states visited. Seventeen of these were sponsored alone or jointly by component medical societies, fourteen by sectional organizations, twenty-five by medical or graduate schools, four by academies of medicine and seven by tuberculosis, heart, diabetes or other health organizations. In forty-six graduate programs the training was largely didactic. In twenty cities practicing physicians were offered opportunities to obtain individual instruction in small groups so that additional clinical experience might be had under supervision. At these centers bedside training was emphasized, the undergraduate facilities of medical schools and of hospitals being opened during one to three week periods. The equivalent of short

Marquette Univ. Sch. Med. and Halls	Out of state and faculty members	Co. Med. Soc. Membership	No	Varies	250	Also cooperates with Wise. Anti-T.B. Assn. and other local scientific groups

term residencies were provided in seventeen medical schools and were projected in two others. In eight states the annual program of the state medical association was devoted substantially to graduate medical instruction and in several others in part to such instruction.³

COURSES OFFERED PHYSICIANS

Instruction offered covered the whole field of clinical medicine and several of the basic sciences. Much interest has been shown in subjects in which recent advances have been made. These included therapeutics, preventive medicine, pneumonia, cancer and syphilis. There was special interest also in subjects in which a practical application of the training might follow. Examples of the latter included obstetrics and pediatrics, general medicine, especially cardiac disease and cardiovascular-renal disease, gastro-enterology and proctology, diabetes, allergy, thyroid disease, tuberculosis, common fevers and communicable diseases. Courses in general surgery, especially in traumatic surgery, minor and emergency surgery, neurosurgery, urology and urologic procedures, anesthesia and varicose veins were especially desired. In gynecology, instruction in endocrine therapy was in considerable demand. In the basic sciences pharmacology, pathology and neuropathology, clinical laboratory procedures, surgical anatomy, neuro-anatomy and physiology were

frequently taught. There seemed to be a conscious effort to avoid the implication that review courses offered practicing physicians were in any way preparatory to specialization.

PHYSICIANS' INTEREST IN TRAINING

Twelve state committees on graduate education have executive officers with fairly accurate records of attendance. In these states approximately 25 per cent of the practicing physicians engaged in some form of graduate instruction over a year's period. Permanent record systems were being developed in some states. Several records indicated that physicians once enrolled for graduate training returned for additional instruction. In one state 80 per cent of the profession had registered for courses sometime during eight years; half of the physicians enrolled two or more times. In another, two thirds of the registrants of one year returned the next year for continuation of their education.

It has been observed also that when graduate work has once been established in an active county medical society it becomes a permanent annual affair. In some states dormant component societies have been revived by the stimulating experiences of extension courses given by prominent guest physicians who appreciated and attempted to meet the demands of physicians practicing in extrametropolitan areas.

The success of such programs seemed dependent on the sustained interest and activity of component medical societies. With few exceptions it may be said that the most practical educational projects encountered thus far have been found in active, progressive and well organized medical societies. This was especially true in rural communities. Moreover, especially fine sectional meetings have been developed by several metropolitan medical societies during the past five years, and for

3. See Graduate Medical Education, Progress Reports of the Field Study on Graduate Medical Education in the United States Being Conducted by the Council on Medical Education and Hospitals, Organization Section of THE JOURNAL: Alabama, May 14, 1938, p. 207B; Connecticut, June 18, p. 241B; Illinois, April 16, p. 186B; Indiana, February 19, p. 114B; Iowa, January 22, p. 40B; Kansas, April 23, p. 193B; Kentucky, May 21, p. 218B; Michigan, February 5, p. 73B; Minnesota, March 5, p. 136B; Mississippi, May 28, p. 226B; Missouri, April 30, p. 200B; Nebraska, April 9, p. 180B; New Jersey, March 19, p. 159B; New York (excluding metropolitan areas), June 11, p. 233B; Wisconsin, January 29, p. 54B; New York (metropolitan areas), volume 111, August 6, p. 542; Tennessee, August 20, p. 725.

more than fifty years sectional organizations in the South have devoted their efforts to continuing the training of physicians.

The success of extension programs in several states seemed dependent on the personal enthusiasm and energy of one or of a few physicians who, at considerable sacrifice to their vocation, were carrying a major share of the responsibilities connected with their state's educational activities.

FINANCING GRADUATE PROGRAMS

In nine states with extension programs of five or more years' duration the annual cost per graduate physician has varied from \$1.39 to \$15. In six of these states the registrants were required to pay fees; three state medical associations had no provisions in their budgets for continuing medical education. Five of the nine states received some federal support for professional training. Four of seven other states with permanent programs had no fixed budget allowances for graduate instruction.

Courses were given by instructors without compensation, except for travel expenses, in nineteen states. Oftentimes it was necessary that small fees be charged in order that announcements, registration, travel expenses of instructors and facilities might be financed. Except for federal funds, which have been used over the past three years, and private educational funds, which have been utilized less frequently, there seemed to be little provision for supporting courses except by registration fees and income from exhibits at graduate assemblies. Unfortunately, instruction given on a voluntary basis sometimes was not enthusiastically received, especially when registration fees were not charged.

In forty-eight of the extension courses reviewed thus far, physicians paid registration fees and component medical societies had provided budgets for graduate instruction in fifteen. Five medical schools contributed set amounts to cooperative programs, and the faculties and facilities of medical schools and private and public hospitals were used freely and frequently. Health departments supported thirty-one courses, and in at least twenty-three programs federal funds were utilized.

The more expensive graduate programs employed full time personnel to organize and register graduate physicians and to give them instruction on the circuit plan, employing field clinicians. Less expensive was the use of fixed teaching centers in extrametropolitan towns situated within convenient distances of practicing physicians and of instructors. This method of extension training seemed adaptable to several sections of this

country. Still less costly from an administrative standpoint were graduate assemblies in metropolitan areas. When bedside instruction of small groups of physicians was attempted, additional charges were sometimes necessary.

Opportunities for graduate study in twenty-three states are listed in the table.

COMMENT

Representative state association committees on medical education have proved helpful in correlating graduate courses for physicians in several states. Extrametropolitan physicians respond to organized programs and show greater interest in maintaining standards of practice than is generally appreciated. In this connection, it is noteworthy that courses in obstetrics and pediatrics were most frequently desired. Records show that in twelve states one of every four physicians engaged in some form of continuation study during one year. This interest is not limited geographically. Instruction is largely voluntary, which accounts for the relatively low registration fees charged. Recently federal funds have been provided for professional training in several states, supplementing some of the permanent programs which exist in two thirds of the states visited. Educational activities of component medical societies should be further encouraged, with the continued cooperation of academies of medicine, district societies, medical schools, extension divisions of universities, departments of health, hospitals and other interested organizations.

A significant development of residency facilities for practicing physicians, patterned similar to the plans which have operated continuously in Buffalo and Brooklyn since 1921 and 1922, is evident throughout the country. One, two week or longer periods of bedside instruction of limited groups with provision in medical schools and in hospitals for board and/or lodging and intimate instructor-graduate student relationships characterize these short term residencies. Such facilities are now available or projected in San Francisco; Chicago; Indianapolis; Kansas City, Kansas; Louisville, Kentucky; Boston; Detroit; Ann Arbor, Michigan; Minneapolis; Kansas City, Missouri; St. Louis; Omaha; Brooklyn; Buffalo; New York City; Rochester, New York; Syracuse, New York; Durham, North Carolina; Saluda, North Carolina, and Nashville, Tennessee. Thus, practicing physicians of thirteen states are provided opportunities for intramural training in courses designed especially for them.

ESSENTIALS OF AN ACCEPTABLE MEDICAL SCHOOL

(Revised to June 1938)

I. ORGANIZATION

A medical school should be incorporated as a nonprofit institution. Its board of trustees should be composed of public spirited men or women having no financial interest in the operations of the school or its associated hospitals. The trustees should serve for fairly long and overlapping terms. If the choice of trustees is vested in any other body than the board itself, that fact should be clearly stated. Officers and faculty of the school should be appointed by the board.

II. ADMINISTRATION

There should be careful and intelligent supervision of the entire school by the dean or other executive officer who, by training and experience, is fitted to interpret the prevailing

standards in medical education and who is clothed with sufficient authority to carry them into effect.

There should be a good system of records showing conveniently and in detail the credentials, attendance, grades and accounts of the students, by means of which an exact knowledge can be obtained regarding each student's work. Records should also be kept showing readily the attendance of students at the teaching hospitals and dispensaries and the maternity and post-mortem cases attended.

The school should require that students be in actual attendance within the first week of each annual session and thereafter. Except for good cause, such as for illness, no credit should be given for any course when the attendance has been less than 80 per cent of the full time.

The school should issue, at least annually, a bulletin setting forth the character of the work which it offers. Such announcement should contain a list of the members of the faculty with their respective qualifications. The courses available should be set forth by departments (anatomy, physiology and so on) showing for each course its number, subject, content, character (lecture, recitation, laboratory or clinic), length of time, when, where and by whom given, and the amount of credit allowed. Information should be given regarding entrance requirements and tuition fees. The names of the students enrolled during the current or previous sessions should also be included.

The number of students to whom an adequate medical education can be given by a college is related approximately to the laboratory and hospital facilities available and to the size and qualifications of the teaching staff. A close personal contact between students and members of the teaching staff results in an efficiency which is not possible in an institution where the number of students is excessive.

Advanced standing may be granted to students for work done in other acceptable medical schools, and in granting advanced standing there should be no discrimination against the school's full course students. Official verification of the student's previous medical work should be obtained by direct correspondence with the school from which he comes, and his preliminary qualifications should also be verified and recorded the same as for freshmen students.

The admission of students to the medical school must be in the hands of a responsible committee or examiner, whose records shall always be open for inspection. Documentary evidence of the student's preliminary education should be obtained and kept on file. When the medical school is an integral part of the university, this work usually devolves on the university examiner. Unless the university examiner and his records are closely accessible, however, some officer at the medical school should obtain and keep on file each student's academic records.

III. FACULTY

The school should have a competent teaching staff, graded and organized by departments. Appointments should be based on thorough training, successful teaching experience, ability in research, and willingness to pursue an academic career. In the clinical departments this does not exclude men who are in the active practice of medicine and surgery. Nominations for faculty positions should originate in the faculty, usually being made by the dean in consultation with the department heads or a committee of the faculty. Reasonable security of tenure must be assured in order that the personnel of the faculty may have adequate stability. In the preclinical sciences the faculty should include at least ten qualified persons of professorial rank,¹ devoting their entire time to teaching and to that research without which they cannot well keep up with the rapid progress of medical science. For each twenty-five students in a class there should be at least one full time assistant in each of the preclinical departments. Salaries should be sufficient to enable members of the faculty to support themselves and their families without the necessity of devoting time and energy to other occupations.

IV. PLANT

The school should own, or enjoy the assured use of, modern fireproof buildings sufficient in size to provide lecture rooms, class laboratories, small laboratories for the members of the teaching staff and advanced students, administrative offices and a medical library. Equipment should be adequate, both for student use and for research. A trained librarian should be employed to supervise the operation and development of the library, which should include the more modern text and reference books with the *Quarterly Cumulative Index Medicus*, the *Index Catalogue of the Library of the Surgeon-General's Office* and serviceable card indexes. The library should receive regularly the leading medical periodicals, the current numbers of which should be readily accessible. These periodicals should be bound without delay.

1. Professorial rank as here used includes professors, associate professors and assistant professors.

There should be provision for the collection, preservation and indexing of anatomic, embryologic, pathologic and other specimens. With each pathologic specimen coming from post mortems there should also be kept the record of the postmortem, the clinical history of the patient on whom the necropsy was held, and microscopic slides showing the minute structure of the disease shown in the gross specimen. The museum furnishes an excellent means of correlating the work of the department of pathology with that of the clinical departments.

There should be sufficient dissecting material to enable each student to dissect at least the lateral half of the human cadaver, to provide cross sections and other material for study and demonstration.

For experimental laboratory work, as well as for medical research, a supply of animals is essential. Proper provision is necessary also for the housing and care of such animals. In any use made of animals every precaution should be taken to prevent suffering, and work by students should be carefully supervised.

Each school should have such useful auxiliary apparatus as stereopticons, reflectoscopes, microprojectors, carefully prepared charts, embryologic or other models, manikins, dummies for use in bandaging, x-ray apparatus, and other aids to effective teaching.

V. CLINICAL FACILITIES

The school may own or control a general hospital. By control is meant the unquestioned right to appoint the attending staff. In this event the students come into close and extended contact with patients under adequate supervision. In the event that a medical school depends for clinical teaching on an independent hospital, it is essential that the clinical teachers, either on nomination by the school or by agreement in conference between school and hospital, be appointed by the hospital trustees to appropriate positions on the hospital staff. Such hospitals should be in close proximity to the school and have a daily average of not less than 200 patients who can be utilized for clinical teaching, these patients to be of such character as to permit the students to see and study the common variety of surgical and medical cases as well as a fair number in each of the so-called specialties. In the use of this material, bedside and ward clinics should be developed for sections of from five to ten students, and patients in medicine, surgery and the specialties should be assigned to each student under a well supervised clinical clerk system. The treatment and care of these patients should be particularly observed and recorded by the student under the strict supervision of the intern, the resident or the attending staff of the hospital. The use of existing municipal or state hospitals for teaching purposes is also advised.

The school should also own or control ample hospital facilities for children's contagious and nervous and mental diseases.

The school should own or control a well ordered dispensary or outpatient department with a daily average attendance of at least 100 patients (visits). Good histories and records of the patients should be kept and the material used in medical instruction. The attending staff should be drawn largely from the faculty, including those of highest rank.

At least fifteen maternity cases should be provided for each senior student, who should have actual charge of these cases under the supervision of the clinical instructor. A carefully prepared report of each case should be handed in by the student.

Facilities should be provided for at least fifty necropsies during each school session which are attended and participated in by students. These should be performed by the professor of pathology or a member of his staff. The material thus secured should be used in connection with clinical pathologic conferences.

VI. RESOURCES

Experience has shown that modern medicine cannot be acceptably taught by a school which depends solely on the income from students' fees. No medical school, therefore, should expect to secure approval which does not have a substantial income in addition to students' fees. This statement carries double weight if the school finds it necessary to maintain its own teaching hospital.

VII. REQUIREMENTS FOR ADMISSION

1. The minimum requirement for admission to approved medical schools is two years of college training which include English, theoretical and practical courses in physics, biology, and general and inorganic chemistry. Three years or more in college is, however, recommended.

2. Since it cannot in general be assumed that all who have satisfied these requirements merely in terms of hourly credits are fitted for the study of medicine, it is desirable that qualitative standards for admission should be imposed.

3. As a rule candidates should have received their preliminary education in institutions approved by accrediting agencies acceptable to the Council. Exception to this rule may be made in the case of applicants who have demonstrated superior ability. For the convenience of admitting officers the Council has prepared a list of colleges of arts and sciences approved by national and regional educational associations.

4. Admission to approved medical schools may also be by examination under the following conditions:

(a) Candidates who have completed two years of collegiate instruction and present evidence of general scholarship of high order, but who lack credits in not more than two of the required subjects, may be admitted on passing examinations in these subjects.

(b) Candidates who have completed three years of collegiate instruction and present evidence of having accomplished work of distinction in one or more fields of learning, but who lack credit in any or all of the required subjects, may be admitted on passing examinations in these subjects.

VIII. CURRICULUM

The entire course of four academic years should consist of from 3,600 to 4,400 hours, distributed as from 900 to 1,100

hours a year, and shall be grouped as set forth in the following schedule, each group to be allotted approximately the percentage of hours of the whole number of hours in the courses as stated:

	Number	Per Cent.
1. Anatomy, including embryology and histology..	14	18.5
2. Physiology	4½	6
3. Biochemistry	3½	4.5
4. Pathology, bacteriology and immunology.....	10	13
5. Pharmacology	4	5
6. Hygiene and sanitation.....	3	4
7. General medicine	20	26.5
Neurology and psychiatry		
Pediatrics		
Dermatology and syphilis		
8. General surgery	13	17.5
Orthopedic surgery		
Urology		
Ophthalmology		
Otolaryngology		
Roentgenology		
9. Obstetrics and gynecology.....	4	5
Total	76	100
Electives	24	0

When the teaching conditions demand it, a subject may be transferred from one division to another.

Several of the medical schools now require an internship for graduation. Where it is not obligatory it is strongly urged and graduates should be assisted in securing internships in hospitals approved by the Council on Medical Education and Hospitals of the American Medical Association.

ESSENTIALS OF AN ACCEPTABLE SCHOOL OF OCCUPATIONAL THERAPY

I. ORGANIZATION

1. A school of occupational therapy should be incorporated under the laws regulating associations operated not for profit. The control should be vested in a board of trustees composed of public spirited men or women having no financial interest in the operation of the school. The trustees should serve for fairly long and overlapping terms. If the choice of trustees is vested in any other body than the board itself, this fact should be clearly stated. Officers and faculty of the school should be appointed by the board.

2. Affiliation with a college, university or medical school is highly desirable but is not an absolute requirement.

3. Schools of occupational therapy should not be operated by hospitals independently. It is understood, however, that hospitals are needed for practice training in the several branches of occupational therapy as required under clinical affiliations.

II. RESOURCES

Experience has shown that an adequate school of occupational therapy cannot be maintained solely by the income from students' fees. No occupational therapy school, therefore, should expect to secure approval which does not have a substantial additional income.

III. FACULTY

The school should have a competent teaching staff, graded and organized by departments. Appointments should be based on thorough education and training and successful teaching experience. The staff should include not less than one regular salaried instructor and one registered occupational therapist. The question of full time and part time appointments is not as important as the qualifications of the instructors, who should be specialists or exceptionally well trained in the lines they are teaching.

IV. PLANT

1. The school should own, or enjoy the use of, buildings sufficient in size to provide adequate lecture rooms, class labora-

tories and administration offices. Equipment should be adequate for efficient teaching in the various departments.

2. A library containing standard texts and leading periodicals in occupational therapy should be provided.

V. ADMINISTRATION

1. SUPERVISION.—There should be careful and intelligent supervision of the entire school by the dean, director or other executive officer who, by training and experience, is fitted to interpret the prevailing standards and who is clothed with sufficient authority to carry them into effect.

2. RECORDS.—There should be a good system of records showing conveniently and in detail the credentials, attendance, grades and accounts of the students, by means of which an exact knowledge can be obtained regarding each student's work. Schools should require that students be in actual attendance within the first week of each annual session and thereafter. Except for good cause, no credit should be given for any course when attendance has been less than 80 per cent.

3. CREDENTIALS.—The admission of students to the occupational therapy school must be in the hands of a responsible committee or examiner, whose records shall always be open for inspection. Documentary evidence of the student's preliminary education should be obtained and kept on file. When the occupational therapy school is an integral part of the university, this work usually devolves on the examiner or registrar.

4. ADVANCED STANDING.—At the discretion of the administration, advanced standing may be granted for work (or experience) required in the occupational therapy curriculum which has been done in other accredited institutions. Official verification of previous work (or experience) should be obtained by direct correspondence. Preliminary qualifications should also be verified and recorded.

5. NUMBER OF STUDENTS.—The number of students admitted to the training course should not be excessive. In practical work of a laboratory nature the number of students that can

be adequately supervised by a single instructor is, in general experience, about fifteen; in lectures the number may be much larger. A close personal contact between students and members of the teaching staff is essential.

6. **DISCIPLINE.**—All training schools reserve the right to drop a student at any time for any cause which the school authorities deem sufficient.

7. **PUBLICATIONS.**—The school should issue, at least biennially, a bulletin setting forth the character of the work which it offers. Such an announcement should contain a list of the members of the faculty with their respective qualifications.

VI. CLINICAL AFFILIATIONS

1. No student should be eligible for entrance into clinical training until she has satisfactorily completed at least one academic year, equal to thirty semester credits, fifteen of which should be in biologic science, social science, theory of occupational therapy and clinical subjects and fifteen in therapeutic occupations.

2. Hospitals or institutions affiliating for clinical training should be carefully judged by the board of directors of the school concerned and be acceptable to the Council on Medical Education and Hospitals and should not be considered eligible for training of students unless the director of the occupational therapy department is a competent occupational therapist qualified to handle students.

3. The occupational therapy director of each training department should be considered a member of a special committee on the training school staff and at all times be in close contact with the director of the school.

4. A well defined program of lectures, clinics and staff meetings should be offered by the hospital to each group of students.

5. Written records, case studies and examinations should be required of each student. Students should obtain satisfactory rating in clinical training before a diploma is granted.

6. Uniform written records specially covering the student's personal adjustment as well as general ability should be kept by the occupational therapy director of each department, regular copy of which should be sent to the school at frequent intervals and all reports filed in the individual student's record at the school.

VII. PREREQUISITES FOR ADMISSION

1. **AGE.**—The admission of candidates should be governed by the fact that it is required that each student be not less than 21 years of age at graduation.

2. **EDUCATION.**—All candidates must furnish proof of having completed a high school education or its equivalent. Equivalent of high school should be adjudged and recorded by the admissions committee of the school. In addition, all candidates, except those for the degree course, must have had at least one year and preferably two years of further accredited education or successful professional training or experience.

Candidates for admission to a training course in a college or university which is combined with work leading to a bachelor's degree should be required to comply with the regular entrance requirements of the institution concerned.

3. **CHARACTER.**—All candidates should be required to present evidence of good character and general fitness, the evidence of which should be investigated and duly weighed by the school concerned.

4. **HEALTH.**—All students should be given a medical examination under the supervision of the school as soon as practicable after admission, and this examination should be repeated annually. The first examination, at least, should include a tuberculin test followed by a roentgen examination of the chest when indicated.

VIII. CURRICULUM

1. **LENGTH OF COURSE.**—The minimum length of the course should be twenty-five calendar months (100 weeks) of full time training. The course should include not less than sixteen months (sixty-four weeks) of theoretical and technical instruction and not less than nine months (thirty-six weeks) of hospital practice-

training under competent supervision; all as set forth in detail in succeeding sections.

2. **DISTRIBUTION OF TIME.**—The two years devoted to theoretical and technical training should include not less than sixty semester hours, of which not less than thirty semester hours should consist of didactic instruction and not less than twenty-five hours of technical instruction in therapeutic occupations.

(a) **Theoretical:** The hours devoted to theoretical training should be still further subdivided as follows:

	Semester Hours
(1) Biologic Sciences to include:	
Anatomy	15
Kinesiology	
Neurology	
Physiology	
Psychiatry	
Psychology	
(2) Social Sciences to include:	
Sociology	4
Delinquency and Crime	
Social and Educational Agencies	
(3) Theory of Occupational Therapy to include:	
Interpretative courses covering the principles and practice of occupational therapy in relation to orthopedics, pediatrics, tuberculosis, psychiatry, general medicine and surgery and other special fields	4
(4) Clinical Subjects to include:	
Blindness and Deafness	4
Cardiac Diseases	
Communicable Diseases (including Bacteriology if this subject is not given elsewhere)	
General Medical and Surgical Conditions	
Orthopedics	
Tuberculosis	
(5) Electives	3
Total	30

(b) **Technical:** Because of the increasing demands of the medical profession for qualified therapists trained in special fields applicable to the education and training of disabled persons as well as to the treatment of the sick, there must be a certain amount of flexibility in technical requirements.

Concentration may be in the field of *Therapeutic Arts and Crafts*, in some branch of *Educational Therapy*, or in *Recreational Therapy*.

A minimum of thirty semester hours should be devoted to technical training. The major portion may be allotted to concentration in one field and, in this case, survey courses should be given in the other fields.

- (1) The Field of Therapeutic Arts and Crafts to include:
Design
Leather
Metal
Plastic Arts
Textiles
Wood
- (2) The Field of Educational Therapy to include:
Adult Education
Fine and Applied Arts
Home Economics
Hospital Library Management
Primary and Secondary Education
- (3) The Field of Recreational Therapy to include:
Dramatics
Gardening
Music
Physical Education
Social Recreation

Advanced standing may be given to students already qualified in one or more branches of the three fields. Such persons may then be given survey courses in the other fields of concentration, and practice in the application of their specialty to the treatment of disabled persons.

(c) **Clinical Affiliations:** The time devoted to hospital practice-training shall be not less than nine months spent in the following types of hospitals:

Mental hospitals	Not less than two months.
Tuberculosis sanatoriums or services	Not less than one month.
General hospitals	Not less than one month.
Children's hospitals or services	Not less than one month.
Orthopedic hospitals or services	Not less than one month.

The remaining three months optional.

APPROVED SCHOOLS FOR OCCUPATIONAL THERAPY TECHNICIANS

Boston School of Occupational Therapy, Boston
Kalamazoo State Hospital School of Occupational Therapy,* Kalamazoo, Mich.
St. Louis School of Occupational and Recreational Therapy, St. Louis
Philadelphia School of Occupational Therapy, Philadelphia

DESCRIPTION OF MEDICAL COLLEGES

ALABAMA

University (Tuscaloosa)

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE.—Organized in 1859 at Mobile as the Medical College of Alabama. Classes graduated in 1861 and subsequent years excepting 1862 to 1868, inclusive. Reorganized in 1897 as the medical department of the University of Alabama. Present title assumed in 1907, when all property was transferred to the University of Alabama. In 1920 clinical teaching was suspended and the medical school was removed to the university campus near Tuscaloosa. Coeducational since 1920. Minimum entrance requirements are three years of collegiate work. The course of study covers two years of thirty-six weeks each. The faculty includes 15 professors and 12 instructors, assistants, etc., a total of 27. The tuition fees are \$271 each year. Each class is limited to fifty students. The registration for 1937-1938 was 91. The next session begins Sept. 15, 1938, and ends May 30, 1939. The Dean is Stuart Graves, M.D.

ARKANSAS

Little Rock

UNIVERSITY OF ARKANSAS SCHOOL OF MEDICINE, 1209 McAlmont Street.—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The faculty consists of 26 professors and 74 lecturers and assistants, total 100. The curriculum covers four years of nine months each. Entrance requirements are two years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The fees for the four years for residents of Arkansas are \$275; nonresidents are charged \$155 additional each year. The registration for 1937-1938 was 298; graduates, 80. The next session begins Sept. 28, 1938, and ends June 6, 1939. The Dean is Frank Vinsonhaler, M.D.

CALIFORNIA

Berkeley-San Francisco

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL, University Campus, Berkeley; Medical Center, San Francisco.—Organized in 1862 as the Toland Medical College. The first class graduated in 1864. In 1872 it became the Medical Department of the University of California. In 1909, by legislative enactment, the College of Medicine of the University of Southern California, at Los Angeles, became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged, and elective chairs in homeopathic materia medica, and therapeutics were provided. Coeducational since organization. Three years of collegiate work is required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. The faculty is composed of 153 professors and 235 associates and assistants, a total of 388. The course covers four years of eight months each, and an additional fifth year consisting of an internship in a hospital or of special work in a department of the medical school. Fees for the four years, respectively, for residents of California are \$277, \$240, \$235 and \$235; nonresidents are charged \$300 additional each year. The registration for 1937-1938 was 247; graduates, 63. The next session begins Aug. 22, 1938, and ends May 20, 1939. The Dean is Langley Porter, M.D., San Francisco.

Loma Linda-Los Angeles

COLLEGE OF MEDICAL EVANGELISTS.—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda, the clinical departments at Los Angeles. Coeducational since organization. The faculty is composed of 55 professors and 263 associates, assistants and instructors, a total of 318. The course covers a period of four years of nine months each and an additional year consisting of an internship in an approved hospital. Sixty-four semester hours of collegiate work are required for admission. The total fees for the four years, respectively, are \$530, \$435, \$530 and \$540. The registration for 1937-1938 was 384; graduates, 102. The next session begins September 5, 1938, and ends June 11, 1939. The Dean is E. H. Risley, M.D., Loma Linda; and the Associate Dean is W. E. Macpherson, M.D., Los Angeles.

Los Angeles

UNIVERSITY OF SOUTHERN CALIFORNIA SCHOOL OF MEDICINE, 3551 University Avenue.—Organized in 1885 as the University of Southern California College of Medicine. First class graduated in 1888. In 1903 it became the Medical Department of the University of California in Los Angeles. In 1909 the College of Physicians and Surgeons, established in 1904, became the Medical Department of the University of Southern California. Its activities were suspended in 1920; reorganized in May 1928, under present title. The faculty consists of 149 professors and 148 instructors, assistants and others, a total of 297. An internship is required for graduation. Three years of collegiate work is required for admission. Coeducational since organization. Annual fees amount to \$452. The registration for 1937-1938 was 190; graduates, 43. The next session begins Sept. 19, 1938, and ends June 10, 1939. The Dean is Paul S. McKibben, Ph.D.

San Francisco

STANFORD UNIVERSITY SCHOOL OF MEDICINE, 2398 Sacramento Street, San Francisco.—Organized in 1908, when, by agreement, the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. The faculty consists of 129 professors and 149 lecturers, assistants, and others, a total of 278. Three years of collegiate work is required for admission. The course covers four years of eight and one-half months, each, plus a fifth year of intern work. The fees for the four years, respectively, are \$470, \$446, \$364 and \$364. The registration for 1937-1938 was 237; graduates, 63. The next session begins September 27, 1938, and ends June 14, 1939. The Dean is Loren Roscoe Chandler, M.D.

COLORADO

Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE, 4200 East Ninth Avenue.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged, Jan. 1, 1911. Coeducational since organization. The faculty is composed of 57 professors and 130 lecturers, instructors and assistants, a total of 187. The course covers four years of nine months each. The entrance requirements are three years of collegiate work. The fees for residents of Colorado, for each of the four years are, respectively, \$271, \$261, \$251 and \$246. Nonresidents are charged \$195 additional each year. The registration for 1937-1938 was 207; graduates, 49. The next session begins Sept. 26, 1938, and ends June 12, 1939. The Dean is Maurice H. Rees, M.D.

CONNECTICUT

New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE, 333 Cedar Street.—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812; instruction began in 1813; first class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1884, the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887, Yale College became Yale University. Coeducational since 1916. The faculty consists of 153 professors and 209 lecturers and assistants, a total of 362. The requirements for admission are three years of collegiate work. The course covers four years of nine months each. The fees for the four years, respectively, are \$505, \$500, \$500 and \$520. The registration for 1937-1938 was 190; graduates, 40. The next session begins Sept. 26, 1938, and ends June 14, 1939. The Dean is Stanhope Bayne-Jones, M.D.

DISTRICT OF COLUMBIA

Washington

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE, 3900 Reservoir Road, N.W.—Organized in 1851. First class graduated in 1852. The faculty is composed of 63 professors, 45 associate professors, 28 assistant professors and 119 instructors; total 263. Required for admission, three years of collegiate work. The course of study covers four terms of eight and one-half months each. The present fees for each of the four sessions, are \$500. The registration for 1937-1938 was 350; graduates, 107. The next session begins Sept. 19, 1938, and ends June 12, 1939. The Dean is David V. McCauley, S.J., Ph.D.

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, 1335 H Street, N.W.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name National Medical College. Classes were graduated in 1826 and in all subsequent years except 1834 to 1838, and 1861 to 1863, inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904, by an Act of Congress, the title of George Washington University was granted to the institution. Coeducational since 1884. The faculty is composed of 57 professors and 111 instructors, demonstrators and assistants, a total of 168. Two years of collegiate work is required for admission. The course covers four years of thirty-six weeks each. The fees for the four years, respectively, are \$550, \$550, \$550 and \$500. The registration for 1937-1938 was 249; graduates, 68. The next session begins Sept. 28, 1938, and ends June 14, 1939. The Dean is Earl B. McKinley, M.D.

HOWARD UNIVERSITY COLLEGE OF MEDICINE, Fifth and W Streets, N.W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The faculty comprises 34 professors and 79 lecturers and assistants, 113 in all. The admission requirements are at least two years of collegiate work. The course covers four years of thirty-three weeks each. The fees for each of the four sessions, respectively, are \$269, \$269, \$259 and \$266. Registration for 1937-1938 was 131; graduates, 23. The next session begins Sept. 26, 1938, and ends June 9, 1939. The Dean is Numa P. G. Adams, M.D.

GEORGIA

Atlanta

EMORY UNIVERSITY SCHOOL OF MEDICINE, 50 Armstrong Street and Druid Hills.—Organized in 1854 as the Atlanta Medical College. Classes graduated 1855 to 1861, when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874.

In 1898 it merged with the Southern Medical College (organized in 1878), taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with the Atlanta School of Medicine (organized in 1905), reassuming the name of Atlanta Medical College. Became the Medical Department of Emory University in 1915; assumed present title in 1917. Three years of collegiate work is required for admission. The faculty consists of 18 professors and 177 associates and assistants, a total of 195. The course of study is four years of thirty-two weeks each. The fees for each of the four years are \$338. The registration for 1937-1938 was 220; graduates, 60. The next session begins Sept. 26, 1938, and ends June 5, 1939. The Dean is Russell H. Oppenheimer, M.D.

Augusta

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE, University Place.—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. Since 1873 it has been known as the Medical Department of the University of Georgia, the name being changed July 1, 1933, to the University of Georgia School of Medicine. Property transferred to university in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. The faculty includes 59 professors and 30 assistants, 89 in all. Three years of collegiate work is required for admission. The course is four years of thirty-four weeks each. The fees for each of the four years are \$185 for residents of Georgia, and \$365 each year for nonresidents. The registration for 1937-1938 was 151; graduates, 34. The next session begins Sept. 21, 1938, and ends June 5, 1939. The Dean is G. Lombard Kelly, M.D.

ILLINOIS

Chicago

LOYOLA UNIVERSITY SCHOOL OF MEDICINE, 706 South Wolcott Avenue.—Incorporated in 1915 as the Bennett Medical College, and operated as an organic part of Loyola University, by virtue of an agreement entered into with the trustees of Bennett Medical College. Present title assumed in 1917. The Chicago College of Medicine and Surgery was purchased in 1917. The first class graduated in 1916. Coeducational. Three years of collegiate work is required for admission. The course of study is five years, including an internship. The B.S. degree in medicine is conferred at the end of the third year. The faculty is composed of 120 in professorial rank and 140 others, a total of 260. The fees for each year are \$450, \$437, \$366 and \$328, respectively. The enrollment for 1937-1938 was 403, graduates, 115. Next session for juniors and seniors begins September 6, 1938, for freshmen and sophomores, September 19, 1938, and ends June 15, 1939. The Dean is Louis D. Moorhead, M.D.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, 303 East Chicago Avenue.—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The faculty comprises 139 professors, 316 associates and instructors, a total of 455. The requirement for admission is three years of collegiate work. The B.S. degree in medicine may be conferred before the end of the senior year. The course covers four years of eight and one-half months each and a fifth year spent in an approved hospital as an intern or in other practical work. The total fees are \$365 each year. The registration for 1937-1938 was 558; graduates, 141. The next session begins Sept. 27, 1938, and ends June 10, 1939. The Dean is Irving S. Cutter, M.D.

THE UNIVERSITY OF CHICAGO MEDICAL SCHOOLS.—The Medical Schools include (a) The School of Medicine of the Division of Biological Sciences and (b) Rush Medical College, both of which are organized within the Division of Biological Sciences. The first two years of the medical course for both are given in the School of Medicine of the Division of Biological Sciences and the last two years are given either in the School of Medicine of the Division of Biological Sciences or in Rush Medical College.

The School of Medicine of the Division of Biological Sciences, Fifty-Ninth Street and Ellis Avenue.—Organized in 1924. The work of the first two years of the medical course has been given on the Quadrangles since 1899, in cooperation with Rush Medical College, and that of the third and fourth clinical years has been given since 1924 with the organization of this medical school and the construction on the Quadrangles of the University hospitals and clinics. Coeducational. The faculty is composed of 98 professors, 132 associates, instructors and others, a total of 230. The requirements for admission are three years of collegiate work. The B.S. degree in medicine may be obtained during the second year. The curriculum covers twelve quarters of work. Students are admitted at the beginning of the autumn quarter. The tuition fee for each of the four years is \$450. The registration for 1937-1938 was 287; graduates, 52. The next session begins Oct. 3, 1938, and ends June 14, 1939.

Rush Medical College, 1758 West Harrison Street.—Chartered in 1837; held first class in 1843. First class graduated in 1844. In 1887 the college became the medical department of Lake Forest University, retaining, however, its self government. This relation was dissolved in April, 1898, and in the same month affiliation with the University of Chicago was established. Coeducational since 1898. In May, 1924, by a new contract, the University of Chicago took over the work of Rush Medical College as a department of the University. Thereafter only clinical work has been offered by Rush Medical College. The work of the first two years is given on the University Quadrangles. Three years of collegiate work are required for admission. The year is divided into four quarters of twelve weeks each; the completion of the work of three of these quarters gives credit for a college year. The requirements for the degree

consists of twelve full quarters of work. The faculty is composed of 149 professors, 157 associates, instructors and others, a total of 297. The tuition fee is \$450 for juniors and \$375 for seniors. Effective autumn 1939 the fee for seniors will be increased to \$450. The registration for 1937-1938 was 262; graduates, 168. The next session begins Oct. 3, 1938, and ends June 13, 1939. The school is in session all year except the month of September.

All correspondence relating to general policies should be addressed to W. H. Taliaferro, Ph.D., Dean of the Division of Biological Sciences, or to A. C. Bachmeyer, M.D., Associate Dean of the Division; that relating to Rush Medical College should be addressed to Emmet B. Ray, M.D., Associate Dean of the Division of Biological Sciences (Rush Medical College); and that pertaining to student questions should be addressed to B. C. H. Harvey, M.D., Dean of Students.

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE, 1853 West Park Street.—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relationship with the university was canceled in June, 1912, and was restored in March, 1913, when the present title was assumed. Coeducational since 1898. Three years of collegiate work is required for admission. The curriculum covers four years of thirty-two weeks each, and a year of internship in an approved hospital. The B.S. degree in medicine is conferred at the end of the second year. The faculty is composed of 143 of professorial rank and 317 associates, instructors and assistants, a total of 460. The tuition is \$150 a year for students who are residents of Illinois; \$225 a year for nonresident students. The registration for 1937-1938 was 634; graduates, 150. The next session begins Sept. 26, 1938, and ends June 9, 1939. The Dean is David J. Davis, M.D.

INDIANA

Bloomington-Indianapolis

INDIANA UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. Coeducational since organization. The faculty consists of 270 professors, lecturers, associates and assistants. Three years of collegiate work is required for admission. The B.S. degree in medicine is conferred. The work of the first year is given at Bloomington and the work of the next three years at Indianapolis. The regular fee for the medical course for all four years is \$205 a year for residents of Indiana, and \$410 for nonresidents. The registration for 1937-1938 was 429; graduates, 87. The next session begins Sept. 17, 1938, and ends June 5, 1939. The Dean at Bloomington is Burton D. Myers, M.D., and the Dean at Indianapolis is Willis D. Gatch, M.D.

IOWA

Iowa City

STATE UNIVERSITY OF IOWA COLLEGE OF MEDICINE, University Campus.—Organized in 1869. First session began in 1870. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. Coeducational since 1870. The faculty is made up of 56 professors, 64 lecturers, demonstrators and assistants, a total of 120. Three years of collegiate work is required for admission. The B.S. degree in the combined course of liberal arts and medicine is conferred. The course of study covers four years of thirty-four weeks each. The tuition fee is \$196 each year for residents of Iowa and \$460 for nonresidents. The registration for 1937-1938 was 369; graduates, 83. The next session begins Sept. 26, 1938, and ends June 5, 1939. The Dean is Ewen Murchison MacEwen, M.D.

KANSAS

Lawrence-Kansas City

UNIVERSITY OF KANSAS SCHOOL OF MEDICINE.—Organized in 1880. It offered only the first two years of the medical course until 1905, when it merged with the Kansas City (Mo.) Medical College, founded in 1894, and the College of Physicians and Surgeons, founded in 1894, and the Medico-Chirurgical College, founded in 1897. Absorbed Kansas Medical College in 1913. First class graduated in 1906. The clinical courses are given at Kansas City. Coeducational since 1880. The faculty includes 59 professors and 135 instructors, assistants and others, a total of 194. The requirement for admission is two years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The course covers four years of nine months each. The total fees for residents of the state for each of the four years are, respectively, \$148, \$147, \$155 and \$157. For nonresidents the fees are \$268, \$337, \$405 and \$407. The registration for 1937-1938 was 289; graduates, 67. The next session begins Sept. 22, 1938, and ends June 12, 1939. The Dean is H. R. Wahl, M.D., Kansas City.

KENTUCKY

Louisville

UNIVERSITY OF LOUISVILLE SCHOOL OF MEDICINE, First and Chestnut Streets.—Organized in 1837 as Louisville Medical Institute. The first class graduated in 1838, and a class graduated each subsequent year except 1863. In 1846 the name was changed to University of Louisville Medical Department. In 1907 it absorbed the Kentucky University Medical Department; in 1908, the Louisville Medical College, the Hos-

pital College of Medicine and the Kentucky School of Medicine. In 1922 it changed its name to the University of Louisville School of Medicine. Coeducational since organization. Two years of collegiate work is the minimum requirement for admission. Preference is given applicants with a degree or three college years leading to a degree. The faculty numbers 74 professors and 95 assistants, instructors and others, a total of 169. Course covers four years of thirty-two weeks each, exclusive of vacations and examinations. Fees for four years are, respectively, \$404, \$404, \$409 and \$419. The registration for 1937-1938 was 342; graduates, 93. The next session begins Sept. 15, 1938, and ends June 3, 1939. The Dean is John Walker Moore, M.D.

LOUISIANA

New Orleans

LOUISIANA STATE UNIVERSITY MEDICAL CENTER, 1542 Tulane Avenue.—Organized January 1931. Coeducational. First session October 1931, with students of first and third year. Faculty comprises 33 professors and 134 assistant professors, instructors and assistants, a total of 167. Course covers four years of no less than 32 weeks each and one year of general rotation or laboratory internship in an approved hospital. A minimum of three years' collegiate work is required for admission. Total fees, \$137 each year for residents of Louisiana; additional tuition of \$400 each year for nonresidents. The registration for 1937-1938 was 307; graduates, 55. The next session begins Sept. 5, 1938, and ends May 27, 1939. The Dean is Rigney D'Aunoy, M.D.

TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE, 1430 Tulane Avenue.—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years except 1863-1865, inclusive. It was transferred to the Medical Department of the University of Louisiana in 1847, and became the Medical Department of the Tulane University of Louisiana in 1884. Present title in 1913. Coeducational since 1915. The faculty comprises 34 professors and 198 associate and assistant professors, instructors and assistants, a total of 232. The course covers four years of thirty-two weeks each. A minimum of two years of collegiate work is required for admission. Total fees for each of the four years, respectively, are \$457, \$447, \$432 and \$442. The registration for 1937-1938 was 468; graduates, 113. The next session begins Sept. 23, 1938, and ends June 7, 1939. The Dean is Charles C. Bass, M.D.

MARYLAND

Baltimore

JOHNS HOPKINS UNIVERSITY SCHOOL OF MEDICINE, Washington and Monument Streets.—Organized in 1887. Offered preliminary course only until 1893. The first class graduated in 1897. Coeducational since organization. The faculty consists of 71 professors and 372 instructors, assistants and others, a total of 443. The requirement for admission is a collegiate degree. The course extends over four years of eight and one-half months each. The total fees for each year are, respectively, \$621, \$620, \$620 and \$620. The registration for 1937-1938 was 281; graduates, 76. The next session begins Sept. 27, 1938, and ends June 6, 1939. The Dean is Alan M. Chesney, M.D.

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE AND COLLEGE OF PHYSICIANS AND SURGEONS, Lombard and Greene Streets.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. Baltimore Medical College was merged with it in 1913. In 1915 the College of Physicians and Surgeons of Baltimore was merged and the present name assumed. Coeducational since 1918. The faculty consists of 45 professors, 72 associate and assistant professors, and 191 instructors and assistants, a total of 308. Three years of collegiate work is required for admission. The course covers four years of eight months each. The fees for the four years, respectively, are: \$485, \$475, \$475 and \$490 for residents of the state; for nonresidents the fees are \$150 additional each year. The registration for 1937-1938 was 373; graduates, 102. The next session begins Sept. 22, 1938, and ends June 3, 1939. The Dean is J. M. H. Rowland, M.D.

MASSACHUSETTS

Boston

BOSTON UNIVERSITY SCHOOL OF MEDICINE, 80 East Concord Street.—Organized in 1873 as a homeopathic institution. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The first class was graduated in 1874. Became nonsectarian in 1918. Coeducational since organization. Three years of collegiate work is required for admission. The faculty includes 25 professors, 165 associates and others, a total of 190. The course covers four years. Total fees for each of the four years, respectively, are \$475, \$425, \$425, \$439. The registration for 1937-1938 was 199; graduates, 43. The next session begins Sept. 22, 1938, for 1st, 2d and 3d year students, and Sept. 12, 1938, for 4th year students; and ends June 12, 1939. The Dean is Alexander S. Begg, M.D.

HARVARD UNIVERSITY MEDICAL SCHOOL, 25 Shattuck Street.—Organized in 1782. The first class graduated in 1788. It has a faculty of 151 professors and 427 other instructors and assistants, a total of 578. Two years of collegiate work is required for admission. The total fees for each of the four years is \$420, plus \$5 the first year for matriculation. The registration for 1937-1938 was 520; graduates, 135. The next session begins Sept. 26, 1938, and ends June 22, 1939. The Dean is Charles Sidney Burwell, M.D.

TUFTS COLLEGE MEDICAL SCHOOL, 416 Huntington Avenue.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. Coeducational since 1894. It has a faculty of 81 professors and 295 assistants, lecturers and others, a total of 376. A bachelor's degree is required for admission. The course covers four

years of eight months each. The total fees for each of the four years are \$512, \$507, \$407 and \$417. The registration for 1937-1938 was 419; graduates, 109. The next session begins Sept. 21, 1938, and ends June 19, 1939. The Dean is A. Warren Stearns, M.D.

MICHIGAN

Ann Arbor

UNIVERSITY OF MICHIGAN MEDICAL SCHOOL.—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed in 1915. Coeducational since 1870. It has a faculty of 25 professors, 20 associate professors, 27 assistant professors, 114 assistants, instructors and lecturers; a total of 186. The entrance requirements are ninety semester hours. The curriculum covers four years of nine months each. The total fees for Michigan students are \$220 for each of the four years, respectively; for nonresidents, \$350 a year. The registration for 1937-1938 was 481; graduates, 102. The next session begins Sept. 26, 1938, and ends June 17, 1939. The Dean is A. C. Furstenberg, M.D.

Detroit

WAYNE UNIVERSITY COLLEGE OF MEDICINE, 1516 St. Antoine Street.—Organized at the Detroit College of Medicine in 1885 by consolidation of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, organized in 1880. Reorganized with the title of Detroit College of Medicine and Surgery in 1913. The first class graduated in 1886. In 1918 it became a municipal institution under the control of the Detroit Board of Education. In 1934 the name was changed by the action of the Detroit Board of Education to Wayne University College of Medicine, as a part of the program of consolidation of the Detroit City Colleges into a university system. Coeducational since 1917. Entrance requirement is an academic degree or 90 semester hours of academic credit with "combined degree" guaranteed by school of arts and sciences. The faculty consists of 47 professors, 230 lecturers and others, a total of 277. The course covers four years of nine months each and a fifth year of intern work. The total fees for each of the first four years are, for Wayne County residents \$325, and for nonresidents outside of Wayne County \$425; for the fifth or intern year a diploma fee of \$10. The registration for 1937-1938 was 260; graduates 78. The next session begins Sept. 19, 1938, and ends June 17, 1939. The Dean is Raymond B. Allen, M.D.

MINNESOTA

Minneapolis

UNIVERSITY OF MINNESOTA MEDICAL SCHOOL.—Organized in 1883 as the University of Minnesota College of Medicine and Surgery, reorganized in 1888 by absorption of St. Paul Medical College and Minnesota Hospital College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons, organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged. Present title in 1913. Coeducational since organization. The faculty includes 90 professors and 238 instructors, a total of 328. The curriculum covers four years of nine months each, and a year's internship in an approved hospital. The school is operated on the four-quarter plan. The entrance requirements are two years of university work, which must include six semester credits of rhetoric, eight semester credits of physics; thirteen credits of general chemistry, qualitative and quantitative analysis and organic chemistry, eight credits of zoology, and a reading knowledge of scientific German, with a "C" average in all subjects and in the sciences. Beginning with the academic year 1939-1940 the minimum entrance requirement will be three years of college work with the addition of general psychology, physical chemistry and genetics and eugenics to the above specified courses. Students are required to meet the requirements for a degree of B.S. or B.A. before receiving the degree of Bachelor of Medicine (M.B.), which is granted at the end of the four-year course. The M.D. degree is conferred after a year of intern work, of advanced laboratory work, or of public health work has been completed. Students are graduated at the end of any quarter in which work is completed and examinations passed. Total fees are \$243 for residents and \$393 for nonresidents, each year of three quarters. The registration for 1937-1938 was 469; graduates, 117. The next session begins Sept. 26, 1938, and ends June 17, 1939. The Dean is Harold S. Diehl, M.D.

MISSISSIPPI

University

UNIVERSITY OF MISSISSIPPI SCHOOL OF MEDICINE.—Organized in 1903. Coeducational since organization. Gives only the first two years of the medical course. A clinical department was established at Vicksburg in 1908 but was discontinued in 1910 after graduating one class. The session extends over eight and one-half months. Entrance requirement is three years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The faculty includes 9 professors, 2 assistant professors, 2 adjunct professors, 14 instructors, assistants, and others, a total of 27. The total fees for the first year are \$353, and for the second year \$325. The nonresident fee is \$50 additional each year. The registration for 1937-1938 was 34. The next session begins Sept. 19, 1938, and ends June 5, 1939. The Dean is B. S. Guyton, M.D.

MISSOURI

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE.—Organized at St. Louis in 1845; was discontinued in 1855 but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. Coeducational since 1872. The faculty includes 18 professors and 10 instructors, lecturers and others, a total of 28. The entrance requirements are 90 semester hours of collegiate work. The B.S. degree

in medicine is conferred at the end of the second year. Total fees for the first year are \$150, for the second, \$135. Nonresidents of the state pay \$40 per semester extra. The registration for 1937-1938 was 79. The next session begins Sept. 12, 1938, and ends June 6, 1939. The Dean is Dudley S. Conley, M.D.

St. Louis

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE, 1402 South Grand Boulevard. Organized in 1901 as the Marion-Sims-Beaumont Medical College by union of Marion-Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. First class graduated in 1902. It became the Medical School of St. Louis University in 1903. The faculty is composed of 75 professors and 242 instructors and assistants, a total of 317. The completion of three years of college study is the minimum admission requirement but students presenting meritorious credits in excess of the minimum are accepted by preference. The B.S. degree in medicine, except for those already registered for this degree, has been discontinued (1937). The curriculum covers four years of thirty-two weeks each. The summer is optional and offers courses academically equivalent to those in the regular session. The total fees for the four years, respectively, are \$525, \$525, \$420 and \$455. The registration for 1937-1938 was 461; graduates, 103. The next session begins Sept. 20, 1938, and ends June 1, 1939. The Dean is Alphonse M. Schwittalla, S.J., Ph.D.

WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, Kingshighway and Euclid Avenue.—Organized in 1842 as the Medical Department of St. Louis University. The first class graduated in 1843. In 1855 it was chartered as an independent institution under the name of St. Louis Medical College. In 1891 it became the Medical Department of Washington University. In 1899 it absorbed the Missouri Medical College. Coeducational since 1818. The faculty comprises 116 professors and 218 lecturers, instructors and others, a total of 334. Four years of collegiate work is required for admission. The B.S. degree in medicine is conferred at the end of the third or fourth year. The course is four years of eight months each. The total fees for the four years are, respectively, \$524, \$419, \$419 and \$424. The registration for 1937-1938 was 348; graduates, 96. The next session begins Sept. 22, 1938, and ends June 6, 1939. The Dean is Philip A. Shaffer, Ph.D.

NEBRASKA

Omaha

CREIGHTON UNIVERSITY SCHOOL OF MEDICINE, 306 North Fourteenth Street.—Organized in 1892 as the John A. Creighton Medical College. The first class graduated in 1893. Present title in 1921. Coeducational since organization. It has a faculty of 69 professors and 74 instructors, lecturers and assistants, a total of 143. Two years of collegiate work required for admission. The B.S. degree in medicine is conferred at the end of the second year. The curriculum covers four years of eight months each. The total fees each year for the four years are, respectively, \$393, \$393, \$348 and \$356. The registration for 1937-1938 was 262; graduates, 68. The next session begins Sept. 20, 1938, and ends June 1, 1939. The Dean is Bryan M. Riley, M.D.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE, Forty-Second Street and Dewey Avenue.—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The instruction of the first two years was given at Lincoln and of the last two at Omaha until 1913, when the work of all four years was transferred to Omaha. Coeducational since 1882. The faculty is composed of 71 professors and 52 lecturers and instructors, a total of 123. Three years of collegiate work is required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees for each of the four years, respectively, are \$219, \$214, \$214 and \$214. The registration for 1937-1938 was 319; graduates, 75. The next session begins Sept. 19, 1938, and ends June 6, 1939. The Dean is C. W. M. Poynter, M.D.

NEW HAMPSHIRE

Hanover

DARTMOUTH MEDICAL SCHOOL.—Organized by Dr. Nathan Smith in 1797. The first class graduated in 1798. It is under the control of the trustees of Dartmouth College. Courses of the third and fourth year were discontinued in 1914. The faculty consists of 17 professors and 12 instructors, a total of 29. Three years of collegiate work is required for admission. The course covers nine calendar months in each year, or eight months of actual teaching. Candidates for the A.B. degree in Dartmouth College may substitute the work of the first year in medicine for that of the senior year in the academic department. The fees for the first year are \$460 and \$450 for the second year. The registration for 1937-1938 was 38. The next session begins Sept. 22, 1938, and ends June 16, 1939. The Dean is John P. Bowler, M.D.

NEW YORK

Albany

ALBANY MEDICAL COLLEGE, 47 New Scotland Avenue.—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. In 1915, Union University assumed educational control. Coeducational since 1915. The faculty is composed of 60 professors and 83 instructors, assistants and others, a total of 143. A collegiate degree is required for admission. The curriculum covers four years of eight months each. The total fees for four years, respectively, are \$455, \$430, \$415 and \$415. The registration for 1937-1938 was 110; graduates, 25. The next session begins Sept. 26, 1938, and ends June 12, 1939. The Dean is R. S. Cunningham, M.D.

Brooklyn

LONG ISLAND COLLEGE OF MEDICINE, 350 Henry Street.—Organized in 1858 as the Long Island College Hospital. The first class graduated in 1860 and the last class in 1930. Reorganized with a new charter in 1930 as the present institution. The first class graduated in 1931. Coeducational. It has a faculty of 119 professors, associate, assistant, clinical and assistant clinical professors, and 171 lecturers, associates, instructors, assistants and others, a total of 290. Seventy-two semester hours of collegiate work is required for admission. The course covers four years. The total fee for each of the four years is \$610. The registration for 1937-1938 was 361; graduates, 88. The next session begins Sept. 12, 1938, for fourth year and Sept. 26 for other years, and ends June 10, 1939. The Dean is Jean Alonzo Curran, M.D.

Buffalo

UNIVERSITY OF BUFFALO SCHOOL OF MEDICINE, 24 High Street.—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1898. Coeducational since organization. The faculty is composed of 87 professors and 178 associates, assistants and others, a total of 265. Two years of collegiate work is required for admission. The course covers four years of eight months each. The total fees for each of the four years are, respectively, \$530, \$525, \$520 and \$530. The registration for 1937-1938 was 258; graduates, 58. The next session begins Oct. 2, 1938, and ends June 10, 1939. The Dean is Edward W. Koch, M.D.

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS, 630 West One Hundred and Sixty-Eighth Street.—The medical faculty of Columbia College, then known as King's College, was organized in 1767. Instruction was interrupted by the War of the Revolution. The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807. In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College. This merger became permanent by legislative enactment in 1891. Columbia College became Columbia University in 1896. The medical school has been coeducational since 1917. The faculty is composed of 212 professors and 500 instructors, demonstrators and others, a total of 712. Three years of collegiate work is required for admission. The work covers four years of eight months each. The total fees for the four years, respectively, are \$545, \$530, \$530 and \$550. The registration for 1937-1938 was 405; graduates, 90. The next session begins Sept. 22, 1938, and ends June 6, 1939. The Dean is Willard C. Rappleye, M.D.

CORNELL UNIVERSITY MEDICAL COLLEGE, 1300 York Avenue.—The first year was given at New York and Ithaca but beginning with the session 1938-1939 the entire course will be given in New York. Organized in 1898. Coeducational since organization. The faculty is composed of 120 professors and 288 assistants, lecturers, instructors and others, a total of 408. All candidates for admission must be graduates of approved colleges or scientific schools, or seniors of approved colleges that will permit them to substitute the first year of this medical school for the fourth year of their college course and will confer on them the baccalaureate degree on the completion of the first year's work. The fees for each of the four years are, respectively, \$510, \$500, \$510 and \$525. The registration for 1937-1938 was 283; graduates, 66. The next session begins Sept. 21, 1938, and ends June 7, 1939. The Dean is William S. Ladd, M.D.

NEW YORK MEDICAL COLLEGE AND FLOWER HOSPITAL, Fifth Avenue at 105th Street.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title New York Homeopathic Medical College was assumed in 1869; the title New York Homeopathic Medical College and Hospital in 1887; the title New York Homeopathic Medical College and Flower Hospital in 1903; present title May 11, 1936. The first class graduated in 1861. Coeducational since 1919. A baccalaureate degree or its equivalent required for admission. The course covers four years of eight months each. It has a faculty of 69 professors and associate professors, 22 assistant professors and 217 lecturers and assistants, a total of 308. The total fees for the four years are, respectively, \$645, \$635, \$635 and \$665. The registration for 1937-1938 was 268; graduates, 57. The next session begins Sept. 19, 1938, and ends June 6, 1939. The Dean is Claude A. Burrett, M.D.

NEW YORK UNIVERSITY COLLEGE OF MEDICINE, 477 First Avenue.—Organized in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. Named University and Bellevue Hospital Medical College from 1898 to February 1935 when it was changed to New York University College of Medicine. First class graduated in 1899. Coeducational since 1919. The faculty is composed of 136 professors, associate, assistant, clinical and assistant clinical professors, and 312 lecturers, instructors and others, a total of 448. The course covers four years. Entrance requirements are that all candidates must be graduates of approved colleges or scientific schools, or seniors in good standing in approved colleges or scientific schools on condition that their faculty will permit them to substitute the first year in the New York University College of Medicine for the fourth year of their college course and will confer the bachelor's degree on the satisfactory completion of the year's work. The fees for each of the four years is \$600. The next session begins Sept. 14, 1938, and ends June 7, 1939. The registration for 1937-1938 was 496; graduates, 124. The Dean is Currier McEwen, M.D.

Rochester

UNIVERSITY OF ROCHESTER SCHOOL OF MEDICINE, Elmwood Avenue and Crittenden Boulevard.—Organized in 1925 as the Medical Department of the University of Rochester. Coeducational since organization. The faculty is composed of 60 professors, 175 lecturers, assistants, instructors and others, a total of 235. The work embraces a graded

course of four years of nine months each. Three years of collegiate work is required for admission. The total fees for each year are \$500. The registration for 1937-1938 was 177; graduates, 39. The next session begins Sept. 19, 1938, and ends June 17, 1939. The Dean is George Hoyt Whipple, M.D.

Syracuse

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE.—Organized in 1872, when the Geneva Medical College, chartered in 1834, was removed to Syracuse, under the title "The College of Physicians and Surgeons of Syracuse University." Present title assumed in 1875, when a compulsory three-year graded course was established. The first class graduated in 1873 and a class graduated each subsequent year. In 1889 the amalgamation with the university was made complete. Course extended to four years in 1896. Coeducational since organization. The faculty is composed of 46 professors and 160 associate and assistant professors, lecturers and instructors, a total of 206. Three years of a recognized college course is required for admission. The course covers four years of thirty-four weeks each. The fee for each of the first three years is \$500; for the fourth year, \$510. The enrolment for 1937-1938 was 176; graduates, 36. The next session begins Sept. 22, 1938, and ends June 5, 1939. The Dean is H. G. Weiskotten, M.D.

NORTH CAROLINA

Chapel Hill

UNIVERSITY OF NORTH CAROLINA SCHOOL OF MEDICINE.—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department at Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. Coeducational since 1914. Three years of collegiate work is required for admission. The B.S. degree in medicine is conferred at the end of the first year. The faculty is composed of 14 professors and 7 instructors, a total of 21. The fees for each year are \$295 for residents; nonresidents, an additional fee of \$100. The registration for 1937-1938 was 65. The next session begins Sept. 15, 1938, and ends June 6, 1939. The Dean is Wm. deB. MacNider, M.D.

Durham

DUKE UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1925. The first class was admitted, Oct. 1, 1930. Coeducational. The faculty is composed of 11 professors and 106 associate and assistant professors, lecturers, instructors and assistants, a total of 117. The entrance requirements are seventy hours of collegiate work. The academic year consists of four quarters of eleven weeks each. Students either may study four quarters each year after the first year, and if satisfactory will receive the M.D. certificate after three and one quarter calendar years, or three quarters in each year, and if satisfactory will be graduated after four calendar years. The B.S. degree in medicine may be conferred for special work after six quarters. Students are urged to spend three years in hospital or laboratory work after graduation and must give assurance satisfactory to the executive committee that they will spend at least two years. The fees are \$450 for each year of three quarters. The registration for 1937-1938 was 252; graduates, 47. The next session begins Sept. 29, 1938, and ends June 5, 1939. The Dean is Wilburt C. Davison, M.D.

Wake Forest

WAKE FOREST COLLEGE SCHOOL OF MEDICAL SCIENCES.—Organized in 1902. The faculty numbers 11 professors, 2 assistant professors, and 7 instructors, making a total of 20. Coeducational since 1927. The name was changed from the School of Medicine to the School of Medical Sciences in 1937, in view of the fact that it offers only the first two years of the medical course, which is made up largely of the medical sciences. Ninety semester hours of collegiate work is required for admission. Each annual course extends over nine months. The fees for each of the two years are \$300. The registration for 1937-1938 was 41. The next session begins Sept. 14, 1938, and ends May 30, 1939. The Dean is C. C. Carpenter, M.D.

NORTH DAKOTA

Grand Forks

UNIVERSITY OF NORTH DAKOTA SCHOOL OF MEDICINE.—Organized in 1905. Offers only the first two years of the medical course. Coeducational since organization. Three years' work in a college of liberal arts is required for admission. The B.S. degree in combined arts-medical course is conferred at the end of the second year. The faculty consists of 8 professors and 8 instructors, a total of 16. The fees are \$75 each year for resident students and \$165 for nonresidents. The registration for 1937-1938 was 48. The next session begins Sept. 19, 1938, and ends June 6, 1939. The Dean is H. E. French, M.D.

OHIO

Cincinnati

UNIVERSITY OF CINCINNATI COLLEGE OF MEDICINE. Eden and Bethesda Avenues. Organized in 1909 by the union of the Medical College of Ohio (founded in 1819) with the Miami Medical College (founded in 1852). The Medical College of Ohio became the Medical Department of the University of Cincinnati in 1896. Under a similar agreement, March 2, 1909, the Miami Medical College also merged with the University when the title of Ohio-Miami Medical College of the University of Cincinnati was taken. Present title assumed in 1915. Coeducational since organization. Candidates for admission to the freshman class must present three years of college preparation of not less than ninety hours. All candidates taking premedical work at the College of Liberal Arts, University of Cincinnati, must sign up for the seven-year combined course, and at the end of one year of satisfactory work in the College of Medicine the B. S. degree is granted by the College of Liberal Arts. The faculty consists of

50 professors and associates, 412 assistants, etc., a total of 462. The course covers four years of eight months each, on the completion of which the M.B. degree is granted. A year's internship in an approved hospital is required, on completion of which the M.D. degree is granted. Beginning with the fall session of 1938-1939 the fees are as follows: For legal residents of Cincinnati, \$450 a year, plus laboratory fees, (\$50 additional for those not legal residents of Cincinnati). The registration for 1937-1938 was 294; graduates, 72. The next session begins Sept. 23, 1938, and ends June 9, 1939. The Dean is Alfred Friedlander, M.D.

Cleveland

WESTERN RESERVE UNIVERSITY SCHOOL OF MEDICINE, 2109 Adelbert Road.—Organized in 1843 as the Cleveland Medical College in cooperation with Western Reserve College. The first class graduated in 1844. It assumed the present title in 1881. In 1910 the Cleveland College of Physicians and Surgeons was merged. Coeducational since 1919. The faculty includes 84 professors and 228 lecturers, assistants and others, a total of 312. The curriculum covers three years of nine months each and one year of ten months. Three years of collegiate work is required for admission and a baccalaureate degree for graduation. The total fees for each of the four years are, respectively, \$442, \$425, \$415 and \$425. The registration for 1937-1938 was 270; graduates, 63. The next session begins Sept. 22, 1938, and ends June 14, 1939. The Dean is Torald Sollmann, M.D.

Columbus

OHIO STATE UNIVERSITY COLLEGE OF MEDICINE, Neil and Eleventh Avenues.—Organized in 1907 as the Starling-Ohio Medical College by the union of Starling Medical College (organized in 1847 by charter granted by the State Legislature changing the name from Willoughby Medical College, which was chartered March 3, 1834) with the Ohio Medical University (organized 1890). In 1914 it became an integral part of the Ohio State University with its present title. Coeducational since organization. The faculty consists of 68 professors, associate and assistant professors, 84 lecturers, instructors, demonstrators and others, a total of 152. Three years of collegiate work is required for admission. The course covers four years of thirty-four weeks each. Tuition fees are \$246, \$231, \$231 and \$231 each year, respectively, for residents of Ohio, and \$150 additional for nonresidents. The registration for 1937-1938 was 331; graduates, 92. The next session begins Oct. 4, 1938, and ends June 12, 1939. The Dean is J. H. J. Upham, M.D.

OKLAHOMA

Oklahoma City

UNIVERSITY OF OKLAHOMA SCHOOL OF MEDICINE.—Organized in 1900. Gave only the first two years of the medical course at Norman until 1910, when a clinical department was established at Oklahoma City. The first class graduated in 1911. Coeducational since organization. Since September, 1928, the entire course has been given at Oklahoma City. It has a faculty of 29 professors, 30 associate professors, 13 assistant professors, 38 associates, 14 lecturers, 40 instructors, and 16 assistants, a total of 185. Two years of collegiate work is required for admission. The entrance requirement will be raised to three years effective September 1939. The B.S. in medicine degree is conferred at the end of the second year. The course covers four years of nine months each. The total fees for the four years are, respectively, \$128, \$95, \$53 and \$58. For students residing outside of the State of Oklahoma there is an additional fee of \$250 a year. The registration for 1937-1938 was 223; graduates, 52. The next session begins Sept. 19, 1938, and ends June 5, 1939. The Dean is Robert U. Patterson, M.D.

OREGON

Portland

UNIVERSITY OF OREGON MEDICAL SCHOOL, Marquam Hill.—Organized in 1887. The first class graduated in 1888, and a class graduated each subsequent year except 1898. The Willamette University Medical Department was merged in 1913. Coeducational since organization. It has a faculty of 79 professors and 190 lecturers, assistants and others, a total of 269. Entrance requirements are three years of collegiate work. The course covers four years of thirty-three weeks each. The total fees for the four years are, respectively, \$320, \$315, \$310 and \$316 for residents of Oregon, and \$60 a year additional for nonresidents. The registration for 1937-1938 was 253; graduates, 55. The next session begins Oct. 3, 1938, and ends June 3, 1939. The Dean is Richard B. Dillehunt, M.D.

PENNSYLVANIA

Philadelphia

THE HAHNEMANN MEDICAL COLLEGE AND HOSPITAL OF PHILADELPHIA, 235 North Fifteenth Street.—Organized in 1848 as the Homeopathic Medical College of Pennsylvania. In 1869 it united with the Hahnemann Medical College of Philadelphia, taking the latter title. Assumed present title in 1885. The first class graduated in 1849. Two years of collegiate work in a college of arts and science is required for admission. It has a faculty of 90 professors and 125 lecturers, instructors, and others, a total of 215. The work covers four years of eight months each. Fees for each of the four years are, respectively, \$515, \$512, \$512 and \$535. The registration for 1937-1938 was 548; graduates, 129. The next session begins Oct. 3, 1938, and ends June 15, 1939. The Dean is William A. Pearson, M.D.

JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA, 1025 Walnut Street.—Organized in 1825 as the Medical Department of Jefferson College, Canonsburg, Pa. It was chartered with its present title in 1838. Classes have been graduated annually beginning 1826. In 1838 a separate university charter was granted without change of title, since which time it has continued under the direction of its own board of trustees. It has a

faculty of 77 professors, associate and assistant professors and 172 associates, lecturers, demonstrators and instructors, a total of 249. Four years of college work and a bachelor's degree are required for admission. The course of study covers four years of eight and one-half months each. The total fees for the four years are, respectively, \$445, \$435, \$425 and \$425. The registration for 1937-1938 was 498; graduates, 134. The next session begins Sept. 20, 1938, and ends June 2, 1939. The Dean is Henry K. Mohler, M.D.

TEMPLE UNIVERSITY SCHOOL OF MEDICINE, Broad and Ontario Streets.—Organized in 1901. The first class graduated in 1904. Coeducational since organization. The faculty numbers 33 professors and 196 associates, assistants and others, a total of 229. Three years of collegiate work is required for admission. The fees for each of the four years, respectively, are \$485, \$455, \$435 and \$455. The registration for 1937-1938 was 441; graduates, 113. The next session begins Sept. 21, 1938, and ends June 15, 1939. The Dean is William N. Parkinson, M.D.

UNIVERSITY OF PENNSYLVANIA SCHOOL OF MEDICINE, Thirty-Sixth and Pine Streets.—Organized in 1765. Classes were graduated in 1768 and in all subsequent years except 1772 and 1775-1779, inclusive. The original title was the Department of Medicine, College of Philadelphia. The present title was adopted in 1909. It granted the first medical diploma issued in America. In 1916 it took over the Medico-Chirurgical College of Philadelphia to develop it as a graduate school. Coeducational since 1914. The faculty consists of 108 professors, associate and assistant professors, and 346 lecturers, associates, instructors and others, a total of 454. Three years of collegiate work is required for admission. The course covers four years of thirty-three weeks each. The tuition fee is \$500 each year, with a deposit fee of \$15, a general fee including student health of \$15 and a matriculation fee of \$5. The registration for 1937-1938 was 500; graduates, 139. The next session begins Sept. 26, 1938, and ends June 14, 1939. The Dean is William Pepper, M.D.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, Henry Avenue and Abbottsford Road, East Falls.—Organized in 1850. Classes were graduated in 1852 and in all subsequent years except 1862. It has a faculty of 48 professors and 69 assistants, lecturers, and others, in all, 117. Three years of collegiate work is required for admission. The curriculum covers four years of eight and one-half months each. Total fees for each of the four years are, respectively, \$440, \$433, \$433 and \$455. The registration for 1937-1938 was 106; graduates, 25. The next session begins Sept. 21, 1938, and ends June 14, 1939. The Dean is Martha Tracy, M.D.

Pittsburgh

UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE, Bigelow Boulevard.—Organized in 1886, as the Western Pennsylvania Medical College and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910. The first class graduated in 1887. Coeducational since 1899. The faculty is composed of 29 professors and 282 associates, assistants and others, a total of 311. Entrance requirements are two years of collegiate work. The course of study is four years of eight months each. The total fees for the four years, respectively, are \$500, \$485, \$485 and \$500. The registration for 1937-1938 was 230; graduates, 61. The next session begins Sept. 19, 1938, and ends June 14, 1939. The Acting Dean is W. S. McElroy, M.D.

SOUTH CAROLINA

Charleston

MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA, 16 Lucas Street.—Organized in 1823 as the Medical College of South Carolina. The first class graduated in 1825. In 1832 a medical college bearing the present title was chartered and the two schools continued as separate institutions until they were merged in 1838. Classes were graduated in all years except 1862 to 1865, inclusive. In 1913, by legislative enactment, it became a state institution. Coeducational from 1895 to 1912, when privileges for women were withdrawn, being restored in 1917. It has a faculty of 41 professors and 37 lecturers, instructors and others, a total of 78. The course covers four years of eight months each. Three years of collegiate work is required for admission. The total fees are \$270 each year. Fees for nonresidents of the state, \$420 each year. The enrollment for 1937-1938 was 164; graduates, 42. The next session begins Sept. 22, 1938, and ends June 1, 1939. The Dean is Robert Wilson, M.D.

SOUTH DAKOTA

Vermilion

UNIVERSITY OF SOUTH DAKOTA SCHOOL OF MEDICAL SCIENCES.—Organized in 1907. Coeducational since organization. Offers only the first two years of the medical course. Three years' work in a college of liberal arts is required for admission. Students who complete the third year of premedical work in the College of Arts and Sciences at the University of South Dakota may apply the work of the first year of medicine to the A.B. degree. The B.S. degree is conferred at the end of the second year on those students who do not hold a previous Bachelor's degree. The faculty numbers 14. The tuition is \$100 each year for residents and \$200 for nonresidents. The registration for 1937-1938 was 31. The next session begins Sept. 14, 1938, and ends June 5, 1939. The Dean is Joseph C. Ohlmacher, M.D.

TENNESSEE

Memphis

UNIVERSITY OF TENNESSEE COLLEGE OF MEDICINE, 874 Union Avenue.—Organized in 1876 at Nashville as Nashville Medical College. First class graduated 1877, and a class graduated each subsequent year. Became Medical Department of University of Tennessee in 1879. In 1909 it united with the Medical Department of the University of Nashville to form the joint Medical Department of the Universities of Nashville and Tennessee. This union was dissolved in 1911. The trustees

of the University of Nashville by formal action of that board named the University of Tennessee College of Medicine as its legal successor. In 1911 it moved to Memphis, where it united with the College of Physicians and Surgeons. The Memphis Hospital Medical College was merged in 1913. Lincoln Memorial University Medical Department was merged in 1914. Coeducational since 1911. The faculty includes 101 professors and 136 assistants, instructors and others, a total of 237. Two years of collegiate work is required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees are \$120 quarterly. For residents of the state the charge is reduced \$50 each quarter. The registration for 1937-1938 was 437; graduates, 105. During the academic year of 1938-1939 the quarters begin July 6, Sept. 22, Dec. 30 and March 20, and end Sept. 21, Dec. 14, March 18 and June 10. The Dean is O. W. Hyman, Ph.D.

Nashville

MEHARRY MEDICAL COLLEGE, Eighteenth Avenue North and Heffernan Street. (For Negro Youth).—This school was organized in 1876 as the Meharry Medical Department of Central Tennessee college, which became Walden University in 1900. First class graduated in 1877. Obtained new charter independent of Walden University in 1915. Coeducational since 1876. The faculty is made up of 32 professors and 25 instructors, demonstrators, lecturers and others, 57 in all. Two years' work in a college of liberal arts is required for admission. The curriculum covers four years of thirty-two weeks each. Tuition fees are, respectively, \$295, \$275, \$275 and \$285 each year. The registration for 1937-1938 was 206; graduates, 35. The next session begins Oct. 1, 1938, and ends June 2, 1939. Dean is Edward L. Turner, M.D.

VANDERBILT UNIVERSITY SCHOOL OF MEDICINE, Twenty-First Street at Edgehill.—This school was founded in 1874. The first class graduated in 1875. Coeducational since September 1925. The faculty numbers 223. For matriculation, students must be graduates of collegiate institutions of recognized standing or seniors in absentia, who will receive the bachelor degree from their college after having completed successfully at least one year of work in the school of medicine. The course covers four years of nearly nine months each. The total fees for the four years, respectively, are \$415, \$415, \$415 and \$420. The registration for 1937-1938 was 199; graduates, 48. The next session begins Sept. 27, 1938, and ends June 14, 1939. The Dean is Waller S. Leathers, M.D.

TEXAS

Dallas

BAYLOR UNIVERSITY COLLEGE OF MEDICINE, 810 College Avenue.—Organized in 1900 as the University of Dallas Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University. It acquired the charter of Dallas Medical College in 1904. Coeducational since organization. The first class graduated in 1901. The faculty consists of 99 professors and 95 instructors and assistants, a total of 194. Entrance requirements are two years of collegiate work. The course covers four years of eight months each. The fees for each of the four years, respectively, are \$364, \$354, \$349 and \$374. The registration for 1937-1938 was 302; graduates, 73. The next session begins Oct. 1, 1938, and ends June 5, 1939. The Dean is W. H. Moursund, M.D.

Galveston

UNIVERSITY OF TEXAS SCHOOL OF MEDICINE, 912 Avenue B.—Organized in 1891. The first class graduated in 1892. Coeducational since organization. It has a faculty of 41 professors and 16 lecturers and instructors, a total of 57. The curriculum covers four years of eight months each. The entrance requirement is three years of collegiate work. The total fees for the four years, respectively, are \$88, \$92, \$100 and \$102. There is a matriculation fee of \$50 for each year. The registration for 1937-1938 was 371; graduates, 80. The next session begins Oct. 1, 1938, and ends May 31, 1939. The Dean is W. S. Carter, M.D.

UTAH

Salt Lake City

UNIVERSITY OF UTAH SCHOOL OF MEDICINE.—Organized in 1906. Coeducational since organization. Gives only first two years of medical course. Each school year covers thirty-six weeks. Three years of collegiate work is required for admission. The medical faculty consists of 8 professors, 3 instructors, 16 lecturers, demonstrators and fellows and 2 technicians; a total of 29. The fees per year are \$229. There is a non-resident fee of \$25 per quarter. The registration for 1937-1938 was \$8. The next session begins Sept. 26, 1938, and ends June 2, 1939. The Dean is L. L. Daines, M.D.

VERMONT

Burlington

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE, Pearl Street, College Park.—Organized with complete course in 1822. Classes graduated in 1823 to 1836, inclusive, when the school was suspended. It was reorganized in 1853 and classes were graduated in 1854 and in all subsequent years. Coeducational since 1920. It has a faculty of 48 professors and 31 lecturers, instructors, preceptors and others, a total of 79. Two years of collegiate work is required for admission. The course of study covers four years of nine months each. For residents of Vermont the tuition fee is \$300 each session. Nonresidents are charged an additional \$75 each session. A student activity fee of \$30 is charged all students not holding academic degrees or in attendance four years previously, and a \$25 fee for the doctor's degree. The registration for 1937-1938 was 144; graduates, 38. The next session begins Sept. 16, 1938, and ends June 12, 1939. The Chairman of the Committee of Administration is E. H. Buttle, M.D.

VIRGINIA
Charlottesville

UNIVERSITY OF VIRGINIA DEPARTMENT OF MEDICINE.—Organized in 1827. Classes were graduated in 1828 and in all subsequent years except 1865. Coeducational since the session of 1920-1921. It has a faculty of 38 professors and 37 lecturers, instructors, assistants and others, a total of 75. Two years of collegiate work is required for admission. For residents of Virginia the total fees for the four years, respectively, are \$414, \$391, \$366 and \$361. Nonresidents are charged an additional \$50 each year. The registration for 1937-1938 was 247; graduates, 56. The next session begins Sept. 15, 1938, and ends June 12, 1939. The Dean is J. Carroll Flippin, M.D.

Richmond

MEDICAL COLLEGE OF VIRGINIA, Twelfth and Clay Streets.—Organized in 1838 as the Medical Department of Hampden Sydney College. Present title was taken in 1854. In 1913 the University College of Medicine was merged. In 1914 the North Carolina Medical College was merged. Coeducational since 1918. Classes were graduated in 1839 and in all subsequent years. It has a faculty of 68 professors and 107 lecturers, instructors and others, a total of 175. Three years of collegiate work is required for admission. The course covers four years of eight and one-half months each. Total fees for the four years, respectively, are \$338, \$338, \$323 and \$353. Nonresidents are charged an additional \$125 each year. The registration for 1937-1938 was 295; graduates, 76. The next session begins Sept. 6, 1938, for the first year class; Sept. 16, 1938, for all other classes, and ends June 6, 1939. The Dean is Lee E. Sutton Jr., M.D.

WEST VIRGINIA**Morgantown**

WEST VIRGINIA UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1902, gives the first two years of the medical course. Coeducational since organization. Three years of collegiate work is required for admission. The B.S. degree in medicine is conferred at the end of the second year. Session extends through nine months. Faculty numbers 24. Fees for residents of the state, \$254; nonresidents, \$404, each year. The registration for 1937-1938 was 41. The next session begins Sept. 13, 1938, and ends June 3, 1939. The Dean is Edward J. Van Lier, M.D.

WISCONSIN**Madison**

UNIVERSITY OF WISCONSIN MEDICAL SCHOOL, 412 North Charter Street.—Organized in 1907. Gave only the first two years of the medical course until 1925, when the clinical years were added. Coeducational since organization. Three years of collegiate work are required for admission. The B.S. degree in medical science is conferred at the end of the first year. It has a faculty of 64 professors and 67 lecturers, instructors and others, a total of 131. The fees for each year are, respectively, \$212, \$192, \$165 and \$110. An additional fee of \$200 each year is charged nonresidents. The registration for 1937-1938 was 298; graduates, 52. The next session begins Sept. 21, 1938, and ends June 19, 1939. The Dean is William S. Middleton, M.D.

Milwaukee

MARQUETTE UNIVERSITY SCHOOL OF MEDICINE, 561 North Fifteenth Street.—Organized in December, 1912, by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. Coeducational since organization. It has a faculty of 159. Three years of collegiate work is required for admission. The curriculum covers four years of eight and a half months each, and one year's internship in an approved hospital. The fees for the first year are \$412; for each of the three following years, \$400. The registration for 1937-1938 was 324; graduates, 65. The next session begins Sept. 26, 1938, and ends June 14, 1939. The Dean is Eben J. Carey, M.D.

CANADA**Alberta**

UNIVERSITY OF ALBERTA FACULTY OF MEDICINE, Edmonton.—Organized in 1913. Coeducational since organization. Has given the complete six-year medical course since 1924. The faculty includes 23 full time and 40 part time professors, instructors, assistants and others, a total of 63. Tuition for the first year is \$150, for the second, third and fourth years, \$215; for the fifth and sixth years, \$225. The registration for 1937-1938 was 221; graduates, 31. The next session begins Sept. 27, 1938, and ends April 30, 1939. The Dean is Allan C. Rankin, M.D.

Manitoba

UNIVERSITY OF MANITOBA FACULTY OF MEDICINE, Bannatyne Avenue, Winnipeg. Organized in 1883 as Manitoba Medical College; first class graduated in 1886, and a class graduated each subsequent year. The college transferred all its property to the University of Manitoba in 1919 and assumed the present title. Coeducational since organization. The faculty includes 26 professors and 80 instructors and assistants, total of 106. Matriculation requirements include two years of collegiate work in the faculty of arts and science of a recognized university. The course extends over four years of eight months each and a hospital internship. The total fees for the five years, respectively, are \$276, \$271, \$271, \$271 and \$145. The registration for 1937-1938 was 222; graduates 49. The next session begins Sept. 16, 1938, and ends May 18, 1939. The Dean is A. T. Mathers, M.D.

Nova Scotia

DALHOUSIE UNIVERSITY FACULTY OF MEDICINE, Halifax.—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College, in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the university. First class graduated in 1872. Coeducational since 1871. It has a faculty of 26 professors and 40 demonstrators, lecturers and others, a total of 66. Requires for matriculation two years of arts. The medical course covers four years and a hospital internship of one year. The fees are \$317, \$317, \$317, \$307 and \$307 for each year, respectively; \$250 additional registration fee payable by students outside the British Empire. The registration for 1937-1938 was 178; graduates, 32. The next session begins Sept. 13, 1938, and ends May 16, 1939. The Dean is H. G. Grant, M.D.

Ontario

QUEEN'S UNIVERSITY FACULTY OF MEDICINE, Kingston.—Organized 1854, first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 56. The fee for the first year is \$208 and \$230 for each of the other five years. The course covers six years of thirty teaching weeks each. The registration for 1937-1938 was 292; graduates, 54. The next session begins Sept. 29, 1938, and ends May 24, 1939. The Dean is Frederick Etherington, M.D.

UNIVERSITY OF TORONTO FACULTY OF MEDICINE, Toronto.—Organized in 1843 as the Medical Faculty of King's College. Abolished in 1853. Reestablished in 1887. In 1902 it absorbed Victoria University, Medical Department, and in 1903 it absorbed the Medical Faculty of Trinity University. Coeducational since 1903. The course of study covers six years of eight months each. The B.Sc. (Med.) degree is conferred at the end of the third or sixth year. It has a faculty of 71 professors and 363 lecturers, associates and others, a total of 434. The fees are \$201 for the first year; for the second, \$376; \$271 for the third year; \$296 for the fourth and fifth years, and \$328 for the sixth year. The registration for 1937-1938 was 811; graduates, 119. The next session begins Sept. 27, 1938, and ends May 13, 1939. The Dean is W. E. Gallie, M.D.

UNIVERSITY OF WESTERN ONTARIO MEDICAL SCHOOL, Ottawa Avenue, London.—Organized in 1881 as the Western University Faculty of Medicine; first class graduated in 1883, and a class graduated each subsequent year. Present title in 1923. The medical school has been under the control of the Board of Governors of the University of Western Ontario since 1913. Coeducational since 1913. The faculty numbers 88. The course of study covers six years of eight months each. The total fees to residents of Canada for the last four years, respectively, are \$225, \$225, \$233 and \$258. The registration for 1937-1938 was 212; graduates, 33. The next session begins Sept. 19, 1938, and ends May 13, 1939. The Dean is F. J. H. Campbell, M.D.

Quebec

LAVAL UNIVERSITY FACULTY OF MEDICINE, Quebec.—The Quebec School of Medicine, organized in 1848, became in 1852 the Laval University Faculty of Medicine; first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 81. The fees for each of the medical years are \$175 for residents of Canada. Nonresidents are charged an extra fee of \$175 each year. The premedical requirement is a B.A. degree or its equivalent. The registration for 1937-1938 was 307; graduates, 41. The next session begins Sept. 20, 1938, and ends May 31, 1939. The Dean is P. C. Dagneau, M.D.

MCGILL UNIVERSITY FACULTY OF MEDICINE, 3640 University Street, Montreal.—Founded in 1823 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No session between 1836-1839, owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop's College. Coeducational since 1919. Three years of collegiate work is required for admission. The length of the medical course is four years followed by one year of internship. The faculty consists of 55 professors and 161 lecturers and others, a total of 216. The total fees for each of the four medical years are \$393. The registration for 1937-1938 was 477; graduates, 97. The next session begins Sept. 1, 1938, and ends June 1, 1939. The Dean is A. Grant Fleming, M.D.

UNIVERSITY OF MONTREAL, FACULTY OF MEDICINE, 1265 St. Denis Street, Montreal.—Organized in 1843 as the Montreal School of Medicine and Surgery. In 1891, by act of Parliament, The Medical Faculty of Laval University (organized in 1878) was absorbed. Present name by act of Parliament in 1920. A class was graduated in 1843 and each subsequent year. Coeducational since 1925. The faculty numbers 125. B.A. or B.S. degree, or equivalent, is a prerequisite to our premedical year, which itself precedes a five year medical course. The total fees for each of the five years respectively are \$246, \$227, \$267, \$240 and \$218. The registration for 1937-1938 was 187; graduates 41. The next session begins Sept. 15, 1938, and ends June 15, 1939. The Director of Studies is George H. Baril, M.D., and the Dean is Albert Le Sage, M.D.

Saskatchewan

UNIVERSITY OF SASKATCHEWAN SCHOOL OF MEDICAL SCIENCES, Saskatoon.—Organized in 1926. Coeducational. Offers the first two years of the medical course. Students require three more years of medicine for graduation. Two years of collegiate work is required for admission. The B.S. degree in medicine is conferred at the end of the second year. The medical faculty includes 7 professors and 3 lecturers and assistants, a total of 10. The fees are \$150 for each year. The registration for 1937-1938 was 47. The next session begins Sept. 26, 1938, and ends May 12, 1939. The Dean is W. S. Lindsay, M.B.

HOSPITALS APPROVED FOR TRAINING INTERNS

The following general hospitals containing 227,821 beds are considered in position to furnish acceptable internships for medical graduates. These hospitals are automatically approved for general, or mixed, residency training.

HOSPITALS, 729. INTERNSHIPS, 7,354

The terms used in the column "Type of Internship" are defined as follows:

1. Rotating internships include services in medicine, surgery, pediatrics, obstetrics and in the clinical and x-ray laboratories.

2. Straight internships are limited to a single field.

3. Mixed internships are those comprising more than one service but which do not include all of the six branches which constitute a rotating internship.

NOTES

1. Women interns admitted.
2. Women interns only.
- * Majority of patients available for teaching purposes.
- (a) In lieu of maintenance.
- (b) Salary established by government pay tables.
- (c) \$30 per month second year.
- (d) Bonus of \$110.
- (e) Bonus of \$50.
- (f) Bonus of \$250.
- (g) Bonus of \$100.
- (h) Bonus of \$120.
- (i) Bonus of \$20.
- (j) Bonus of \$300.
- (k) Bonus of \$25.
- (l) Bonus of \$150.
- (m) \$10 per month second year.
- (n) \$25 per month second year.
- (o) \$25 per month first year; \$50 per month second year; bonus of \$100.
- (r) Bonus of \$50.

- (s) Bonus of \$40.
- (t) \$15 per month second year.
- (u) \$25 per month for 4 months; \$30 per month for 8 months; bonus of \$100.
- (v) Bonus of \$125.
- (w) Bonus of \$30.
- (x) \$20 per month to seniors after completion of 12 months' service.
- (y) Bonus of \$50 first year; \$100 second year.
- (z) Bonus of \$75.
- (aa) Net salary \$75 per month. Appointments made by Chief of Office, The Panama Canal, Washington, D. C.
- (bb) Prefer aspirants going into foreign missions or boys born and raised in Hawaii.
- (cc) All internships reserved for the fifth year students of the College of Medicine, University of the Philippines.
- (dd) \$25 per month after first 6 months; \$50 per month second year.
- (1-a) January, July, October.

- (1-b) January, March, July, September, November.
- (1-c) Quarterly.
- (1-d) Every two months.
- (1-e) January, May, September.
- (1-f) January, April, July.
- (1-g) April, July, October.
- (1-h) Medicine: January, April, July, October; surgery: March, June, September, December.
- (1-i) January, April, May, July, September, October.
- (1-j) April, July, September.
- (1-k) Medicine: February, June, October; surgery: every other month; pathology and roentgenology, July.
- (1-m) Every six weeks.
- (1-n) January, April, July, September.
- (1-o) March, June, September, December.
- (1-p) March, July, November.
- (1-q) February, June, October.
- (1-r) July, September, November.

HOSPITALS APPROVED FOR RESIDENCIES IN SPECIALTIES

By the Council on Medical Education and Hospitals

HOSPITALS, 451; RESIDENCIES, 3,700

The following hospitals, conforming to the standards of the Council, furnish acceptable residencies in the several specialties designated. Applicants are required to present evidence of graduation from an approved medical school and completion of at least one year of approved internship. In a few cases, equivalent experience in practice is accepted in lieu of preliminary hospital experience.

Regulations for Certification: It is important to emphasize that residencies alone are not necessarily sufficient preparation for the practice of a specialty. Other types of training are also available and may be required. Candidates should acquaint themselves with the requirements by direct correspondence with the secretaries of the specialty boards.

Statistical Data: The statistical data have been obtained from annual reports covering the calendar year 1937. In a few instances earlier reports have been consulted. In most cases, this information is supplemented in the Council's files by inspection reports and by comments received from residents who have completed the listed service. The data should be examined with the following considerations in mind:

Chief of Service: It is required that there be an organized and qualified staff in the department offering residencies. The names listed are those most recently reported as departmental chairmen. In university hospitals, professors usually are given. Blank spaces indicate recent unconfirmed changes or supervision is supplied by chiefs on parallel or rotating assignments. For personal data see list of physicians in state sections.

Inpatients: The figures refer to total inpatients treated in the specialty. Exceptions are in anesthesia, radiology and pathology where total hospital admissions are used. In obstetrics, some hospitals include new-borns, others do not.

Per Cent Free: An index to charity work performed, although in every instance the majority of patients are available for instruction.

Outpatients: Where available, the service is nearly always required.

Residencies, Assistant Residencies and Length of Appointment: Information supplied indicates whether progressive services are available and over what period of time. The eldest in point of service is the resident and others assistant residents whether so designated by the hospital or not. Senior internships in specialties are classed as assistant residencies.

Salary: It is advisable to confirm the quoted figure when applying. Unless otherwise indicated, compensation includes room and board. In fellowships, the hospital usually supplies maintenance only; the stipend is provided from other sources.

Deaths and Autopsies: These are reported for the specialties. In anesthesia, pathology and radiology, figures are given for the entire hospital. Some obstetrical services include new-born deaths and autopsies.

Important: All hospitals approved for residencies submit names of residents to the office of the Council for permanent credit and registration. It is in the interest of every house officer to assure himself that his name is properly recorded and that the correct dates of all appointments are submitted.

- a. Compensation arranged by medical school and hospital.

b. Salary varies.

c. In lieu of maintenance.

d. Report covers six months only.

e. Hospital facilities by affiliation.

1. Fellowships available.

2. Data as reported for 1936.

3. Mixed residencies represent general hospital experience of at least one year duration following an approved internship. All hospitals approved for intern training are also certified for general or mixed residencies.

4. Includes proctology.

5. Medical and surgical appointments.

6. Dental as well as medical degree required.

7. Research appointments available in medicine and surgery.

8. Includes obstetrics.

9. Includes neurosurgery.

10. Not a hospital; outpatient and home delivery service.
11. Training includes two years of service at City of Detroit Receiving Hospital in gynecology and two years at Herman Kiefer Hospital in obstetrics.

12. Orthopedic resident covers eye, ear, nose and throat service.

13. Apply to chief of service for information about affiliating hospitals.

14. Three assistant residents serve six months in obstetrics.

15. Separate appointments approved in roentgenology and in radiation therapy.

16. Includes dermatology.

17. Several services include obstetrics-gynecology.

18. Private and semi-private pavilions.

19. Admissions are confined to children.

20. No applications received.

21. Affiliating; usually with N. Y. Post-Graduate Medical School, New York City.

22. Includes thoracic surgery.

23. Hospital service confined to treatment of narcotics.

EXAMINERS AND GRADING

In the selection of students for advanced work in college and for the professional schools, the record of previous scholastic aptitude as measured by "grades" is usually an important criterion. The proper interpretation and weight of high school and college grades have become an increasing concern of administrators in universities and professional schools. Hutchinson and Pugh¹ studied the differences in marks assigned not only by different examiners but also by the same examiner in the same subject for the same students at different times. In other words, they examined the examiners, tabulating the marks obtained by a group of twenty-five students in a series of examinations in eight subjects over a period of a year. Grades were recorded according to the decimal system. All the grades in each subject were totaled both for class work and for individual examinations. These totals were then subjected to analysis in relation to several variables, including individual students, individual instructors and the same instructor at different times. The marking for class work was found to be distinctly more lenient than that for examinations in most of the subjects. More surprising were the variations in total marks given by an individual examiner in different tests in the same subject. The higher differential grades for the same group of students in some subjects than in others was also striking. Apparently examiners differed among themselves as much as did the students. It is, however, a simple matter to adjust the students' marks to a common basis by allotting the same total for the class in all subjects. Gross deviations from the accepted standard due to the individual instructor's liberality or strictness in grading can thus be detected and corrected by simple algebraic adjustment.

More serious, Hutchinson and Pugh believe, is the discovery that an examiner often varies widely in his standard of marking the same group in the same

subject after an interval of two or three months. This source of variation is more difficult to control and should receive the attention of those who are responsible for the disposition of candidates for universities or professional schools. This variation in performance of examiners affects the choice of medical as well as other university students. It may affect also the certification of specialists.

Other known factors in student records have already received the consideration of advanced university and professional school administrators. President Conant² of Harvard in a recent report to the Board of Overseers states that there is an ever growing interest in defining each student's aptitudes and interests. As he points out, however, a man's success or failure in a professional school has been proved to be highly correlated with his record of college work. At Harvard the previous school record is corrected for the varying scholastic standards. To such adjustment it would now seem wise to add a factor of correction for those students whose scholastic average has been affected by unjustified variation in grading by examiners. The large extent to which the selection of medical students is influenced by present procedure insures the continued vital interest of the medical profession in this subject.

LOCAL IMMUNIZATION OF THE NASAL MUCOSA

According to Walsh and Cannon¹ of the departments of surgery and pathology, University of Chicago, regional vaccination is the method of choice in the attempt to increase the specific portal resistance of the upper respiratory tract. Local vaccination allegedly gives a much higher concentration of specific antibodies in respiratory tissues than that obtained by active or passive somatic immunization.

The initial studies of local immunity of respiratory tissues by Walsh and Cannon² were made with type I pneumococcus infections in rabbits. They found that nasal instillation of relatively small volumes of virulent pneumococcus cultures into normal rabbits led to a fatal septicemia in about 90 per cent of the cases. Intranasal vaccination with a formaldehyde killed or autolyzed pneumococcus culture of the same type, however, conferred practically complete immunity against subsequent intranasal infection with the same strain. Local nonspecific irritants, such as alum, tannic acid or killed paratyphoid cultures, were without demonstrable effect. Intragastric immunization with the same pneumococcus vaccine gave little or no demonstrable increase in nasal resistance. Since intranasally vaccinated rabbits may have no demonstrable protective

antibodies in the blood stream, as determined by the mouse protection test, the investigators concluded that local vaccination presumably caused a strictly local specific tissue immunity, the nature of which is at present unknown.

In order to throw light on the nature of this local tissue immunity, Walsh and Cannon² extended their studies to include *Bacillus typhosus* and *Bacillus paratyphosus*. Following routine somatic immunization with these vaccines, relatively high specific agglutinin titers develop in the blood stream, with about one tenth of this titer in aqueous extracts of the exsanguinated nasal mucosa. A blood titer of 1:4,000, for example, was usually associated with a 1:500 titer in the nasal extract, or a blood titer of 1:2,000 with a 1:250 tissue titer. A different quantitative relationship was observed after intranasal vaccination. Here the tissue titer humoral titer ratio was usually increased at least two-fold. In many instances the tissue agglutinins were of equal or even greater titer than those of the blood stream.

The investigators are inclined to interpret their results as evidence of a local formation of antibodies in nasal tissues. A qualitative identity of local tissue agglutinins and humoral agglutinins, however, has not yet been established. Conceivably tissue agglutinins and humoral agglutinins are of different specificities. The authors make the general conclusion that "regional vaccination would seem [to be] the preferable method of elevating the level of resistance of tissue at the portal of entry to the body." Whether or not the prophylactic efficiency can be increased by combining regional and somatic vaccination has not yet been determined.

FRANCE MAKES DIPHTHERIA IMMUNIZATION COMPULSORY

The Senate and the Chamber of Deputies of the republic of France passed a regulation making diphtheria immunization compulsory. This was promulgated by the president on June 25. The law reads:¹

Antidiphtheria vaccination with l'anatoxine (toxoid) is compulsory during the second or third year of life. The parents or guardians are personally responsible for the carrying out of this measure, proof of which shall be furnished on admission to any school, nursery, vacation colony, or other assembly of children.

During the first year of application of the present article, all children under 14 years of age attending the schools, if they have not yet been vaccinated against diphtheria, shall be subjected to such vaccination.

The regulations for administration are to be rendered "according to the opinion of the Academy of Medicine and the Consultative Committee on Public Health of France."

This action is apparently the first by a major nation to make diphtheria immunization compulsory and uni-

versal. No penalty clause is attached to the measure as published nor is any authority to establish penalties specifically delegated to the Academy of Medicine and the Consultative Committee on Public Health, although the measure does say that these "shall decide the measures necessitated by the application of the preceding provision." The measure does provide that an immunized child shall not be admitted to any school, nursery, vacation colony or other assembly of children. This leaves an alternative for those persons who may be able to keep their children out of assemblages by employing private tutors or evading compulsory education regulations, such as may exist in France. Obviously, such legislation cannot be enforced without a large force of investigators and administrators.

From the scientific point of view the provision that toxoid shall be administered during the second or third year of life is interesting. The practice in this country, supported by overwhelming consensus of medical and public health opinion, is to advocate diphtheria immunization as early as the eighth month and not later than the first year. This is on the basis of mortality experience. The highest diphtheria mortality is in the first two years of life and there is little mortality after 5. Yet for the first year the French act requires all children under 14 years of age to be immunized against diphtheria and furthermore to be immunized with toxoid. Experience in the United States with untoward reactions following toxoid has led to the general practice of limiting its use to children under 12, toxin antitoxin being used for older persons who, because of special liability to exposure to diphtheria, may require immunization.

Undoubtedly the new law will aid in preventing epidemics if it is even reasonably well enforced. Godfrey² showed that immunization of 30 per cent or more of the children of preschool age will break the chain of infection and prevent epidemics. It will not, however, prevent the appearance of sporadic cases. As diphtheria recedes from the epidemic status it also recedes from the public consciousness. Sporadic cases are more likely to go unrecognized and therefore to be neglected. This causes a trend toward a low morbidity incidence and low mortality on a population basis, but a high case fatality rate.

The experience of the United States with immunization against diphtheria has shown that constructive and persistent local leadership and education are effective in eliminating diphtheria. The experience of France with compulsory immunization should be watched with interest as a comparison. After ten years of observation, which may include two epidemic cycles of uncontrolled diphtheria, the truth about the success or failure of compulsory immunization may be determined.

Current Comment

DOCTORS IN EMBRYO

The annual review of medical education, appearing elsewhere in this issue, presents a summary of the most important phases of medical education in the United States and Canada. These data show the kind and extent of preliminary education which is required for admission to medical schools, also the requirements for graduation and licensure. The number of schools and the number of medical students over a period of more than thirty years show clearly the effects of raising educational standards and, more recently, of the enormous increase of the college population since the war. During the past year there were in the United States 5,194 medical graduates, of whom 237 were women. Some 636 foreign graduates were licensed. Regardless of academic or legal requirements, practically all students serve a hospital internship and many prolong this training by a further period of apprenticeship as hospital residents. The lists of hospitals approved for these purposes is therefore of inestimable value. The supervision of medical schools by the Council on Medical Education and Hospitals through periodic reports and personal visitation is a potent factor in raising the standards of medical education and practice.
